FRIDAY, NOVEMBER 20, 1914.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

ONE-HUNDRED-AND-SIXTY-FIRST SESSION, 1914-1915.

PATRON—HIS MAJESTY THE KING.

COUNCIL.

H.R.H. THE DUKE OF CONNAUGHT AND STRATHEARN, K.G., *President of the Society.*

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., *Vice-President and Chairman of the Council.*

SIR WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., *Vice-Pres.*
VISCOUNT ALVERSTONE, G.C.M.G., D.C.L., LL.D., F.R.S., *Vice-Pres.*
SIR GEORGE RANKEN ASKWITH, K.C.B., K.C., D.C.L., *Vice-Pres.*
SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., *Vice-Pres.*
DUKE OF BEDFORD, K.G., *Vice-Pres.*
SIR GEORGE BIRDWOOD, K.C.I E., C.S.I., M.D., LL.D., *Vice-Pres.*
LORD BLYTH, *Vice-Pres.*
EARL BRASSEY, G.C.B., D.C.L., LL.D., *Vice-Pres.*
ALAN SUMMERLY COLE, C.B.
LORD COWDRAY, *Vice-Pres.*
WILLIAM HENRY DAVISON, M.A., *Treasurer.*
RIGHT HON. SIR HENRY MORTIMER DURAND, G.C.M.G., K.C.S.I., K.C.I.E., *Vice-Pres.*
SIR STEYNING WILLIAM EDGERLEY, K.C.V.O., C.I.E.
PETER MCINTYRE EVANS, M.A.
COLONEL H. C. L. HOLDEN, R.A., C.B., F.R.S.
LORD INCHCAPE, G.C.M.G., K.C.S.I., K.C.I.E., *Vice-Pres.*
SIR JOHN CAMERON LAMB, C.B., C.M.G., *Vice-Pres.*
MAJOR PERCY A. MACMAHON, R.A., LL.D., D.Sc., F.R.S.
SIR PHILIP MAGNUS, M.P.
WILLIAM HENRY MAW, LL.D.
SIR HENRY A. MIERS, M.A., D.Sc., F.R.S., *Vice-Pres.*
LORD MOULTON, M.A., LL.D., F.R.S., *Vice-Pres.*
DUKE OF NORFOLK, K.G., G.C.V.O., *Vice-Pres.*
FRANCIS GRANT OGILVIE, C.B., LL.D.
SIR WESTBY B. PERCEVAL, K.C.M.G., *Vice-Pres.*
ERNEST H. POOLEY, M.A., LL.B., *Vice-Pres.*
SIR BOVERTON REDWOOD, Bart., D.Sc., F.R.S.E.
SIR OWEN ROBERTS, M.A., D.C.L., LL.D., *Vice-Pres.*
LORD SANDERSON, G.C.B., K.C.M.G., *Vice-Pres.*
JOHN SLATER, F.R.I.B.A.
ALAN A. CAMPBELL SWINTON.
CARMICHAEL THOMAS, *Treasurer.*
PROFESSOR J. M. THOMSON, LL.D., F.R.S., *Vice-Pres.*
SIR ASTON WEBB, K.C.V.O., C.B., R.A.
SIR JOHN WOLFE-BARRY, K.C.B., LL.D., F.R.S., *Vice-Pres.*

SECRETARY.

SIR HENRY TRUEMAN WOOD, M.A.

Assistant Secretary—G. K. MENZIES, M.A.
Assistant Secretary for the Indian and Colonial Sections—SAMUEL DIGBY, C.I.E.
Chief Clerk—GEORGE DAVENPORT. *Accountant*—J. H. BUCHANAN. *Auditors*—MESSRS. KNOX, CROPPER & CO.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One Hundred and Sixty-First Session was held on Wednesday evening, November 18th, when an address was delivered by COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Vice-President and Chairman of the Council. (See pp. 6–17, below.)

PAPERS TO BE READ BEFORE CHRISTMAS.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock, unless otherwise announced:—

NOVEMBER 25.—SIR WILLIAM A. TILDEN, D.Sc., F.R.S., F.C.S., "The Supply of Chemicals to Britain and her Dependencies." SIR WILLIAM RAMSAY, K.C.B., LL.D., Sc.D., F.R.S., F.I.C., F.C.S., will preside.

DECEMBER 2.—WILLIAM REGINALD ORMANDY, D.Sc., F.C.S., "Britain and Germany in Relation to the Chemical Trade." The Right Hon. LORD MOULTON, M.A., LL.D., F.R.S., will preside.

„ 9.—WILLIAM A. YOUNG, "Domestic Metal Work of the Eighteenth Century." PROFESSOR WILLIAM GOWLAND, F.R.S., will preside.

„ 16.—SIR WILLIAM DE WIVESLIE ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "Testing Pigments for Permanence of Colour."

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

DECEMBER 17.—DR. F. MOLLWO PERKIN, F.I.C., F.C.S., "The Indian Indigo Industry." SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., will preside.

PAPERS TO BE READ AFTER CHRISTMAS.

F. VINCENT BROOKS, "British Lithography in 1915."

HON. JOHN COLLIER, R.O.I., "Portrait Painting."

THOMAS WORTHINGTON, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. THORNE BAKER, "The Industrial Uses of Radium."

FRANK BAINES, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

G. W. HULME, "Patent Law."

W. T. THORNTON, "The Industrial Uses of Coal Gas."

D. Y. CAMERON, A.R.A., R.E., "Etching."

ROGER FRY, "Post Impressionism in Design."

C. H. SHERRILL, "Ancient Stained Glass."

WILLIAM POEL, "Shakespeare's Profession."

ARTHUR WILCOCK, "Designing for Textiles."

J. A. HUNTER, "The Textile Industries of Germany and of Great Britain."

EDWARD R. DAVSON, "Colonial Sugar Development."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 21, February 18, March 18, April 15, May 13.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

February 2, March 2, 30, May 4.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

R. A. PEDDIE, Librarian, St. Bride Foundation Typographical Library, "The History and Practice of the Art of Printing." Four Lectures.

LECTURE I.—NOVEMBER 23.—*History 1450-1800.* The invention of printing—Types of the early printers—Introduction of illustrations, woodcut borders and initials—The 16th Century a period of great expansion—New styles of type—Popular books—The 17th Century not favourable to the artistic development of the art—The pamphlet and the newspaper supreme—Rigorous press laws—The 18th Century revival—Caslon type—Great printers and their styles—Baskerville, Bodoni, Didot, Ibarra—Bewick and wood-engraving.

LECTURE II.—NOVEMBER 30.—*The 19th Century.* In 1801 no machine production—Stanhope press—Type faces 1801-40—Revival of old style printing and Caslon type—Machine-made paper—Development of the printing machine—Invention of photography—Attempts at colour printing.

LECTURE III.—DECEMBER 7.—*The 19th and 20th Centuries continued.* Woodcuts of the Sixties—Invention of the half-tone—Revival of hand-press work for artistic production—Effect of revival on commercial work—Types and type-founders—Recent inventions in illustration.

LECTURE IV.—DECEMBER 14.—*The later history of colour printing.* Rise of chromo-lithography—Chromo-xylography—The Three-colour process—Collotype—Photogravure and its combinations—The offset process.

DR. F. MOLLWO PERKIN, F.I.C., F.C.S., "Oils, their Production and Manufacture." Three Lectures.
January 18, 25, February 1.

M. H. BAILLIE SCOTT, "House Building—Past and Present." Three Lectures.
March 15, 22, 29.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.
April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evenings, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." Three Lectures.
February 15, 22, March 1.

JUVENILE LECTURES.

These Lectures will be given on Wednesday afternoons, January 6 and 13, at 5 o'clock. The Lecturer and Subject will be announced later on in the *Journal*.

PROCEEDINGS OF THE SOCIETY.

THE SOCIETY was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom: and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country." In 1908 the Society was granted the privilege of adding "Royal" to its title.

FELLOWSHIP.—At the Annual General Meeting held on June 24th, 1914, a By-Law was passed authorising all Members of the Society to use the designation of Fellow.

ORDINARY MEETINGS.—Meetings are held every Wednesday evening during the Session (November to June), at which papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures and Commerce of the country are read and discussed.

INDIAN SECTION.—This Section was established in 1869, for the discussion of subjects connected with the Indian Empire. Six or more Meetings are held during the Session.

COLONIAL SECTION.—This Section was formed in 1874 under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, to include the consideration of subjects connected with the Colonies and Dependencies. Four or more Meetings are held during the Session.

Cantor Lectures.—These Lectures originated in 1863, with a bequest by Dr. Cantor. Several Courses are given during the Session, each Course consisting of two or more Lectures. The Lectures deal with the latest applications of Science and Art to practical purposes, and are, as far as possible, experimentally illustrated.

Howard Lectures.—The bequest of Mr. Thomas Howard (1872) is now devoted to occasional courses of Lectures on motive power and its applications.

Shaw Lectures.—Under the Shaw bequest Lectures on Industrial Hygiene are given from time to time.

Aldred Lecture.—The bequest of the late Dr. Aldred has been devoted to the establishment of an Annual Lecture.

Cobb Lectures.—Funds have been provided for occasional Lectures in memory of the late Mr. Francis Cobb.

Juvenile Lectures.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the children of Fellows during the Christmas holidays.

Admission to Meetings. Fellows have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Fellow can admit two friends to the Ordinary and Sectional Meetings, and to the Cantor and other Lectures. Books of tickets for the purpose are supplied, but admission can also be obtained on the personal introduction of a Fellow. For the Juvenile Lectures special tickets are issued.

Journal of the Royal Society of Arts.—The *Journal*, which is sent free to Fellows, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures and Commerce.

Examinations.—Examinations, founded in 1854, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education and Music. At the 1914 Examinations 29,042 Candidates were examined. Full particulars of the Examinations can be had on application to the Secretary.

Library and Reading-room.—The Library and Reading-room are open to Fellows, who are also entitled to borrow books.

A History of the Society has lately been published (John Murray, pp. 558, 15*s.* net) and can be obtained from any bookseller. It gives a history of the Society's work from 1754 to 1880.

Conversazioni are held, to which Fellows are invited, each Fellow receiving a card for himself and a lady.

Election of Fellows.—Candidates are proposed by Three Fellows, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee.

CALENDAR FOR THE SESSION.

The following is the Calendar for the Session 1914-1915. It is issued subject to any necessary alterations :—

The Cantor Lectures, the Fothergill Lectures, and the Ordinary Meetings, unless otherwise announced, will commence at Eight o'clock.

The Meetings of the Indian Section and the Colonial Section will be held at Half-past Four o'clock.

The Annual General Meeting will be held at Four o'clock.

The Juvenile Lectures will be given at Five o'clock.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 18th, 1914; COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Vice-President and Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Agramonte, Albert Arthur, Assoc.M.Am.Soc.C.E., Direccion de Desagues, Dolores, Argentina, South America.

Baijal, Kewal Ram, Chandni Chowk, Delhi, India.

Baldwin, John Brake, 6, Phillimore-terrace, Kensington, W.

Barth, Jakob Christian, British Vice-Consul, Sundsvall, Sweden.

Bell, William, C.I.E., M.A., 16, Summerside-place, Trinity, Edinburgh.

Bhandarkar, Hon. Chief Justice Vasudeo Gopal, Baroda, Baroda State, India.

Bilstein, Emma L., M.D., The Mount Royal, Baltimore, Maryland, U.S.A.

Bullough, Charles John Robert, The Willows, Warwick Road, Bounds Green, Middlesex.

Burnett, Eric Vaughan, M.Inst.M.M., Villas Harrington No. 7, Camino Cintura, Playa Ancha, Valparaiso, Chili, South America.

Carr, George, 22, Clapton Common, N.E.

Clarkson, Thomas, Talara, Payta, Peru, South America.

de Quesnel, George Marinus, c/o Messrs. Edwards & Sons, 57, Moorgate-street, E.C.

Duggall, Dewan Hari Gopal, Wazirabad, Gujranwala District, Punjab, India.

Dunlap, Professor Frederick, University of Missouri, Columbia, Missouri, U.S.A.

Gould, Charles Newton, Ph.D., 408, Terminal Building, Oklahoma City, U.S.A.

Gray, Mrs. Horace, c/o Messrs. Baring & Co., 8, Bishopsgate-street, E.C.

Gunn, James, 9, Gladstone-street, Hartlepool.

Gupta, Karunakumar Dutta, M.A., B.E., 70, Lansdowne-road, Calcutta, India.

Harrison, Cecil Reeves, B.Sc., Woodcote, Chislehurst, Kent.

Hill, Lewis George, 5, Oxford-road, Acocks Green, Warwickshire.

Langton, Miss Eveline Charlotte, Underhills, Beech-road, Reigate, Surrey.

Lewis, Rev. Edward Pilcher, D.D., St. George's Parsonage, 4 Rua da Estrella, Lisbon, Portugal.

Mackillop, John Archibald, Cumbrae, Mosman, Sydney, New South Wales, Australia.

Mews, John, LL.M., 90, Westbourne-terrace, W.

Munavery, Sahib, Dr. P. M. I., Chalai P.O., Trivandrum, South India.

Narain, Parshottam, Farrukhabad, United Provinces, India.

Nash, Alfred William, Apsheronskaya, Kuban Province, South Russia.

Recke, George Philip, St. Thomas, Danish West Indies.

Rodger, Norman, 2, St. Dunstan's-hill, E.C.

Rogers-Moore, Mrs. Alice, 132, Winsor-avenue, Watertown, Massachusetts, U.S.A.

Royce, William Stapleton, J.P., The Hall, Pinchbeck, Spalding.

Sen, Hon. Rai Bahadur Nisi Kanta, B.L., Purnea, India.

Sircar, D. K., Sukchar Dyeing Factory, Sukchar P.O., 24, Purgannas, Bengal, India.

Skeet, George William, The Blue Coat School, Frome, Somerset.

Smith, Henry Lee, M.A., M.D., 2701, Calvert-street, Baltimore, Maryland, U.S.A.

Taylor, Guy Arthur, B.A., Solwezi, Northern Rhodesia.

Thornton, Horace Moore, The Richmond Gas Stove & Meter Co., Ltd., 132, Queen Victoria-street, E.C.

Westgate, John Minton, United States Department of Agriculture, Washington, D.C., U.S.A.

The CHAIRMAN delivered the following

ADDRESS.

Once again the Council of this Society has done me the honour to make me their Chairman, and it is with the pleasant and satisfactory feeling that I must have been considered as not altogether unworthy of past responsibilities that I now address you at the opening of another session. Since we last met events of world-wide importance have taken place, events which have profoundly affected the normal course of national existence in so many and in such varied ways that one turns naturally to ask the question of any institution or society dependent on voluntary support, "Well, how is it going with you?" We have had time now to think how things are really going, and it will, I am sure, be a lively satisfaction to you all to know that as regards this Society, at any rate, we have nothing to deplore—no unusual decrease either in the number of subscribers or of income generally, and that we commence another session with good hopes, a fair programme, and no regrets. The last session started full of promise, and if we accept the final report on all the varied interests and activities of the Society as drawn up by our indefatigable Secretary, I

think we may fairly claim that the promise was well redeemed. So full and so complete is that report that there is nothing that can be added usefully by me to the general matter of it. But I will claim the privilege, as Chairman, of saying just a few words about one special department of the Society's work, which may, perhaps, be considered as always open to friendly criticism. I refer to the Examinations.

It will be remembered by those of you who follow with interest the progress of the Society's work in this most important branch of it, that it was mainly through the pioneer work of this Society more than sixty years ago that educational centres were established for science and art schools. This led to the formation of school boards, which developed into local educational authorities which control elementary, and, to a certain extent, secondary education throughout this country; and it was the Society's examinations that inaugurated the local examination system which has so greatly promoted the cause of education generally. Now, at last, the Council of this Society, and those educational authorities which owe much to its pioneer work, have been united in a common effort to the same great end; and it is with the assistance and support of the London County Council's educational committee, as well as the very real and satisfactory (if unofficial) help of the Board of Education, that we maintain our present examination system.

Some alterations have been made in such details as the dates on which examinations are held and the arrangement of the syllabus which will be found fully set out in the admirable report of Sir Henry Wood to which I have already alluded, and which is to be found in our *Journal* issue for September 25th. It is not so much to the methods as to the nature of these examinations that I wish to refer. It is a subject of growing importance, for the year 1914 has been a record year for the numbers of examinees, nearly 30,000 having presented themselves for examination. This proves that the value of the Society's diploma as a passport to employment is appreciating from year to year; I think it proves also that on the whole the subjects selected for examination are those which meet the requirements of the time in all three stages of examination (the Advanced, the Intermediate, and the Elementary), and that they secure for those that succeed a real value for their time and study.

The ruling principle of all these examinations is that they should be in subjects which are useful to the commercial life of the individual and of the country. That is the ruling principle, but there are exceptions, as, for instance, the examinations in Music. As this subject falls under no particular commercial head, and appears to be amply provided for by special schools, it may possibly at some future time be discontinued. As regards other subjects, the figures given in the tables accompanying the report show very clearly to what type of the youth of the country our examinations appeal. Book-keeping is the favourite subject; then Shorthand. In both these subjects candidates are numerous and the standard of attainment is high. Arithmetic is not so popular, and it betrays some want of appreciation of its supreme importance in commercial affairs that there should be such a large percentage of failures. But it is the want of interest in those special subjects which happen to interest me individually which naturally attracts my attention most. Commercial History and Geography does not rank high in popular estimation as a subject for study at present. Nor do I expect much from the change of title and the separation of the general subject into two parts—Economic History and Economic Geography. "Economic History" suggests an academic rather than a practical study, and "Economic Geography" hardly explains in itself the enormously wide area of most important knowledge which is so necessary—and often so lacking—in our national commercial ventures.

We are just now agitating ourselves about the best methods of capturing the trade of the great commercial country with which we are at war, which is a sound and legitimate ambition. I am not an authority on commercial matters, but I may, perhaps, be permitted to express an opinion that there are certain, and, indeed, a good many, German industries which we can never hope really to "capture" till we can command cheaper labour. And when it comes to cheapening labour we find ourselves up against trades-unionism. There are others, however (and here I can speak with a certain amount of experience), which are ours to recover, which we have allowed to lapse into German hands by our want of attention to some at least of those elementary trade principles which should be included in a study of Economic Geography. Economic Geography, if it means anything at all as a study, means the careful study of countries in the matters of

geographical environment of any trade area; of the idiosyncrasies, methods, and wants of the inhabitants, the means of terrestrial communication and of intelligent converse. It must, I fear, be admitted that we do not so much trouble about ascertaining the actual wants of a community as teaching them what they ought to want. Why, for instance, in South America has more than one important trade passed out of our hands into those of the Germans? Why is it that with a people fully alive to the advantages of British seamanship the great German liners have taken so much of the first-class traffic? If you ask the reason why in the place where these things occur, you will have several reasons advanced, but they all are based on that one initial failing of ours, *i.e.*, that we do not study the wants of those with whom we are dealing, or make proper allowances for geographical conditions other than our own.

The want of appreciation shown for such a practical study as this seems to indicate that we draw our candidates almost entirely from a class which is in immediate concern for a livelihood. It is that which will lead to immediate employment which is perforce the matter of most importance. Book-keeping, shorthand and typing are the accomplishments which lead most directly to the office stool, and we must content ourselves with the assurance that we are ourselves studying the matter of local requirement, and helping those who want our help most An appeal to the results of language examinations indicates the same concern for immediate advantage, and it is questionable whether examinations in Russian, Danish, Norwegian, Swedish, Japanese, Chinese, Arabic and Hindustani should not be placed on a new basis altogether. Each candidate in these subjects has cost the Society something like 30*s*., and in the last four of these languages not one has attracted more than ten candidates during the last six years. That the percentage of failure this year in such a language as Hindustani should be 100 per cent. is melancholy reading. It means that only one candidate went up and that he failed. This is rather surprising, considering the enormous extent of English commercial industry that exists in India, and the undoubted financial attractions of that country. It rather proves again that there is a lack of both interest and ability in the teaching of Commercial Geography, when such ignorance is practically manifested of India's possibilities. It is suggested with good reason that examinations in these eight languages should be discontinued in future, unless at least twenty-five candidates present themselves.

Following the precedent established of late years in the opening address of the session, I will now turn to a subject of general interest with which I have been more immediately and specially concerned.

Amongst the minor forms of art with which this Society is concerned, and one which deserves more attention from the public than it receives, is the art of map-making. With this form of art I have been associated for many years, and I may therefore be permitted to call your attention to some of those features of it on which I consider that public attention could be usefully directed. I say this because the public is rapidly becoming more and more dependent on map information for the prosecution of commercial enterprise as much as for the proper understanding of great political and military events, to say nothing of the daily requisition of guiding maps in the widespread activities of touring about this country in motors, or about the world at large in steamers and railways. We cannot do without maps nowadays. International disputes—even if they do not culminate in war—require cartographical illustration in the daily papers; and if they do culminate in war, no discussion of military events would be acceptable for an instant without its map. And we can all read maps more or less. Even the most illiterate yokel who can ride a bicycle will have a map in his pocket, and every boy scout is taught to make a map of his own district.

The public is therefore much concerned with maps, and it is a very curious feature of this universal demand that it has been so long in developing in civilised countries. A savage often possesses the instinct of rudimentary map-making — that is to say, he has the fundamental instinct in him which certain animals (I might say all wild animals) have for direction. I remember once searching for an old and disused salt cave on the Persian coast which was said to be inhabited by devils and other unpleasant inhabitants, and which possessed extraordinary subterranean scenery of great wonder and beauty. It was a very hot and a very weary quest. An officer of the telegraph steamer of the Indo-European service was with me. We should, I think, have abandoned the search amongst the low hills which crowded down to the shore line, but that we observed a ragged and scantily

clothed individual sitting in solitude on the shore with a suspicious lump of something before him which he was guarding carefully. The practised eye of my companion observed a native craft on the blue horizon, which he rightly conjectured to be engaged in illicit salt traffic, and we at once found a way out of our trouble. The man on the shore could speak no sort of dialect that either of us knew, and we could only point helplessly to the lump of salt and to the hills, and insinuate by means of certain coins that we were not there to interfere with him, we only wanted to see where that salt came from. So with his fingers he drew a map on the sand, and he did it so well that half an hour's climbing led us into the narrow mouth of the cave, and we saw there what I believe no other European had ever seen. I am not here to talk about salt caves, or I would tell of the extraordinary beauty of that great natural cathedral of salt, with its chancel, its chapels, its screens and pillars of fantastic design and exceeding beauty, and the long subterranean gallery where, through a forest of twisted salt pillars which we lit up with blue lights, we found our way finally by a small and exceedingly narrow exit right out on to the shore once again.

The point of the story lies in the fact that precisely the same symbolism, the alphabet of map-making, came as naturally to the hand of that smuggler as it has to the hand of all map-makers since the days of Ptolemy till now. The map-making of Ptolemy is before us still, and may be studied in the archives of the British Museum. There will the map curator and secretary of the Hakluyt Society (Mr. Villiers) tell you that the very earliest maps of which there is any record are those of Claudius Ptolemeus, which were made about 100 to 150 A.D.; but the earliest copies of them to which we can refer did not exist till about the year 1400, thirteen centuries after they were actually compiled, at a time which was almost coeval with the invention of printing. Copies of his maps, which accompanied a geographical treatise, were made from time to time, one or two of which are in the British Museum. The 1400 copy contains a map which is a creditable representation of Britain not including Ireland, which is separate. The 1450 copy again leaves Ireland out of Britain and makes too much of Scotland. The 1470 copy includes Ireland with the British Isles, and is a great improvement on the preceding copies.

But there were other maps during the thirteen centuries which elapsed between the making and the publishing of Ptolemy's maps, and some of them are remarkably interesting. St. Jerome's translation of the Greek work, "Onomasticon," A.D. 388, deals with Biblical countries. A famous map of the world was compiled by a Spanish monk, St. Beatus, in A.D. 776. This makes the earth square, plants the Garden of Eden at the top of the map (which is the eastern side of it), with Eve and the serpent in orthodox relationship. The next important map is the "Cotton"—or Anglo-Saxon—map of the world, dating from about the end of the tenth century. Here Jerusalem is no longer the centre—and Taprobana, or Ceylon, is at the top. A map dating from 1200 again places Jerusalem in the centre, but from the Garden of Eden at the top there flow out five rivers, the Ganges being included. This is a diminutive map designed to illustrate a psalter, but room is found in it for a great variety of human monstrosities such as are common to all mediæval maps. These remarkable additions to mediæval mapping are really interesting as indications of the nature of the ethnographical knowledge of the time. It is quite probable that they represent the prevailing ideas of the educated—*i.e.*, of the priestly—class regarding the strange living world beyond their immediate ken. About the year 1350, and for a century later, there was a popular history in England written by a monk at Chester called the "Polychronicon," and in it there are two maps compiled in the conventional style of the day full of Biblical legends and popular myths, with Jerusalem still in the centre, and Noah's Ark resting on the Armenian mountains close at hand. The Amazons, by the way, are depicted as living in North Asia instead of South America. Some of the legends are excellent. We learn that the Tigris, the Nile, and the Euphrates all really rise in Paradise, and only make a secondary appearance in this world.

Coupled with much information of ethnological interest about men with one eye or with hairy bodies, we find these curious facts stated for the enlightenment of posterity. Germany, it is said, has a greater population than it is able to feed, whilst Ireland is both larger and wider than England; it seeks liberty but *shirks work*. One of the latest of the mediæval manuscript maps in the British Museum is a copy of a map compiled in 1459 by Fra Mauro. "Its geography," says Mr. Villiers, "shows an immense improvement on the last map of 1350, Europe being especially good."

Being 6 ft. 4 ins. in diameter, it is full of detail, and many of the old myths and legends are disposed of. Jerusalem is not in the centre of the map, but due apology is made for this fact by the learned monk, who explains that Jerusalem is really to be regarded as the centre of the earth, if we judge not by values of longitude so much as by density of population. Then followed the immortal invention of printing and the reproduction of Ptolemy's maps, which were rightly regarded as a revelation "equal in importance to all the real geographical discoveries that were being made in that important century."

Of the earliest printed maps just one or two require a short reference. There is the map known as the "Cusa" map, compiled before 1464, which is printed from a copper-plate by Cardinal Nicolas of Kuesan, which was the chief map of its time; and a map of the world in the "Insularium illustratum" of Henricus Marletus Germanus is to be noted as the first showing Portuguese discoveries. At this point in map history commence the first rudiments of modern cartography. A Dutch printed map by Johannes Ruysch first represents India as a peninsula. That was in 1507, and it indicates the gradual progress of geographical knowledge. The Waldseemuller map of about the same date introduces the New World, and further defines Portuguese discoveries; and yet another Dutch map (for the Dutch may claim to be pioneers in this branch of the art of printing), usually known as Jan Severseen's map, which undoubtedly is much indebted to the Waldseemuller map for its material, is quite a good example of early topographical art. The mountains now assume the appearance of lines of haycocks, and the trees indicating forests are all of the pointed Noah's Ark variety. Strange beasts, including an enormous elephant, stray over the continents, and monsters of the deep indicate the perils of the sea. Thenceforward the gradual evolution of the printed map passed into the hands of Italians, who took a much stronger lead in geographical illustration than in geographical discovery. Gerard Mercator, at the end of the sixteenth century, was the great map-maker of his day, and his projection (notable, perhaps, for its simplicity) is in use at the present time. Mercator gives us by far the best map of Ireland yet produced. The first panorama of London city was, strange to say, issued from a printing office in Amsterdam in 1616. It was executed by Nicolas Visscher, the engraver, and shows Bow Church in the centre; Billingsgate on the east; Hampstead on the north; and, quite naturally and rightly, the Globe theatre on the south.

So far I have dealt with some of the most interesting maps to be found in the British Museum, but I am bound to observe that the reproduction of photographs of these and other maps on the screen of the lecture-room at the Royal Geographical Society last April was hardly a success, owing to the generally illegible nature of the writing on the face of the maps and the overcrowding of detail. It was impossible in the space of one or two minutes to identify even the leading geographical features (which naturally differed widely in contour from any modern representation), and a full appreciation of the value of the information contained in them is only to be obtained by careful perusal of the originals.

It is to be regretted that the greatest geographers of the mediæval ages (the Arabs) have left so little in the shape of cartographical illustration behind them. And yet I must admit that I have found such indications of ancient geography of the East as were recorded in a form which merely gave the approximate bearings of old-world cities in parts of Western Asia from each other (without any attempt to pourtray the contour or the features of the countries concerned), a most useful guide in reviving the story of the old cities of the Persian and Afghan borders. There was, of course, the invaluable assistance of original description, and it was from this description (containing a very approximate estimate of distances between remarkable points) by the great traveller, Ibn Haukel, who travelled in the tenth century of our era, that the small and crude map was probably compiled in its original form. As we gradually developed a general geographical survey of the districts in question this little map was often sufficient to guide me to the almost unrecognisable site of some city of the past which had once been a commercial centre and an important unit in the great scheme of the mediæval Arab trade-routes.

It is an unfortunate fact that there is, so far as I know, no cartographical society in England. The art of map-making deserves more public recognition than it receives, and its gradual development from ancient beginnings is at least an historical record well worth preserving in an accessible form. There is no doubt a feature common to all these old-world maps which cannot be admitted now, but which we can only part with with regret. Pictorial imagination

played a considerable part in their production, and if there is no art without imagination then we must relegate the question of art to the pourtrayal of topographical features in our modern maps, where at least imagination still holds a certain position. But the old-world endeavour to unite ethnographical knowledge to that of more prosaic geography is no longer considered admissible. In fact, it is the extraordinary wealth of an infinite variety of information conveyed by legend and by pictorial illustration which renders the old form of mapping so interesting and so confusing. There are indeed certain details which may be considered as historically useful. We learn something of what our forefathers knew about the world they lived in. We learn what their shipping was like, even if we cannot admit their sea-born monstrosities. We have found that in some details of geographical information they possessed a knowledge of facts which have been discarded since their time, only to be revived again as correct in modern days—as, for instance, in the case of the Nile sources and the mountains of Central Africa. Even in the matter of ethnography there are certain little and apparently insignificant facts recorded in long past days on the face of the map which teach us something of the conservatism of the savage, and lead us to appreciate the mighty length of days which must have elapsed with the gradual evolution of civilisation.

I may mention one curious little incident which records the habits of certain of the coast Indians in the extreme south of South America. I do not know when first the representation of these Indians in their canoes with a fire lighted at the bottom of the canoe appears on the face of the world map. But the "Canoe" Indians still persist in this ancient method of rendering themselves independent of the camp on land, and they still take their wives and families with them, doing their cooking, and living their lives, in an open canoe. The hereditary process of paddling has resulted, too, in an enormous development of muscle in the upper half of their naked bodies, whilst their legs approach the proportions which the tail bears to the tadpole, a fact which also did not escape the notice of early voyagers and map-makers. Again, the giants of Patagonia, although they have degenerated somewhat from the days of early discovery, are still very fairly represented by the tall and athletic Tehuelchi. I was quite satisfied with the impression which they might have left on the minds of early discoverers never averse from startling discoveries, and accepting *omne ignotum pro magnifico.*

With the gradual evolution of a system of cartography which should first of all divide land spaces from water by outlining the continents and islands of the globe, and thereafter separate mountain systems from plains, and secure some representation of the hydrography of the earth by delineating the course of great rivers, there arose the imperative necessity for a form of projection of the map, the definition of parallels of latitude and meridians of longitude by means of which the true relationship of separate areas of the earth could be correctly maintained. Obviously this necessitated careful measurement of the earth's surface in order to determine its figure and to establish laws and formulæ whereby these parallels and meridians could be laid down accurately previous to the introduction of topography. Thus arose the science of geodesy, or earth measurement. Into this highly scientific and technical subject I do not propose to enter. It belongs to the domain of science rather than art, and I will do no more than just indicate its purpose in map-making. It cannot be too strongly insisted on that all sound map-making must be based on sound geodetic measurement in the first instance. Because geodesy is so highly scientific in its various processes of observation and deduction, and appeals so strongly to the mathematician, it has too often been carried out as if it were rather a matter of academic research than as the very bedrock and basis of that most utilitarian of purposes—the making of an accurate map.

To put it shortly. Triangulation, which is the outcome of geodesy, is called upon to supply the framework or skeleton on to which the topography of the body of the map has to be filled. This framework is furnished with a projected graticule system (*i.e.*, with lines of latitude and longitude correctly defined), so that the picture or plan of the country in question can be carefully adjusted by means of the points fixed by the triangulation, which are, of course, common to both the geodetic projection and the topographical map. This adjustment is the work of the cartographer. Sometimes, as in India, the cartographer and the actual topographical surveyor in the field are one and the same person. Sometimes, as in Russia, a highly practised cartographical artist is employed to take the field sheets from the hand of the topographer and translate them to the finished

map without reference to the surveyor at all. I have seen this done both in Russia and in this country. It is this latter method, doubtless, which produces the most artistic effects, but it should be remembered that topography is not only an art, but a twofold art. There is the cartographic art of translating the field map to the final sheet for publication, and there is the art, which long experience has taught me to be a heaven-sent gift (like any other artistic grace) only really given to few, of representing Nature on the field-map as she actually exists—that is to say, in all the manifold beauty of sharply-chiselled mountain, rounded hills and undulating plain, with truth and accuracy. The usual method of representation is, as I have said, conventional. Certain symbols (with which I will deal presently) must represent certain facts, but in all art there are certain conventional laws which must be followed and by which the genius of the artist is circumscribed, unless indeed he is a futurist or a cubist, or his genius has otherwise overstepped the limits of sanity.

The art of the topographer thus combines that of the painter and the engraver; he must have eyes to see, not merely the delicate indications of changing slope and relative altitude, but he must carry in the eye of his mind a fairly clear idea of what all that he sees represents in plan, what he would see in fact were he to fly over the country in an aeroplane. And then he must have the delicate touch of the true draftsman to translate his vision into black and white; a grasp of the relative importance of things and of the capacity of his scale, neither introducing confusion of detail nor omitting important features, subordinating his appreciation of relative importance to the object for which the map is being fashioned, either military or political, or simply agricultural and cadastral as the case may be. It is hardly necessary, I should hope, in these days to explain what is meant by plane-tabling. It is many years now since I had the honour of introducing the first plane-table to a military audience at the Royal United Service Institution in England, where it was regarded with the suspicion which attaches itself to the unknown, although it had been in use for years before my time both in India and on the Continent. I need hardly say that when I talk of making map pictures from Nature, I am talking of the plane-table method of making them. It is the one process which fully deserves the appellation of art, and the beauty and advantage of this system of map-making is that it appeals to the highest artistic instincts. I do not mean that an inartistic effort may be inaccurate or useless. By strict adherence to conventional rules any one may learn to make good use of a plane-table, and I may say here that no one who has learnt to use it will ever adopt any other method of representing either local plans, forest areas, mountain systems or geographically widespread areas, unless there are absolutely prohibitive conditions of climate and atmosphere.

To the true artist the call of his work is insistent. Toil and danger will be ignored for the supreme effort at seeing just that little further, of pourtraying just that little more which is to round off an effective area of map work. If you had seen, as I have, hundreds of field maps carrying geographical mapping far afield into new countries teeming with difficulties, maps, too, which bore an impress of truth on the face of them (an impression which is not to be described but which only experience can recognise), you would wonder with me at the strange fascination which the explorer's work must have for him, seeing that it will lead him to face dangers and difficulties which he might easily count as insuperable without being reckoned a shirker and occasionally beckon him on to the last great sacrifice of all his life. If accuracy is our object, then no professional cartographer, however gifted with artistic imagination and draftsman's skill, can take the place of the man who sees and knows, into whose eyes the picture of great world-spaces has entered. Unfortunately, gifts of imagination combined with draftsman's skill often make very pretty showing. Experience will enable a clever cartographer, a draftsman who has never been in the field, to represent even complicated topographical features of an imaginary character with a skill such that even an experienced surveyor can hardly detect the lies in it; and so it comes about that if a map is to be judged by its accuracy and faithfulness to Nature, apart from artistic effect, it is very often the most unattractive maps that are the best. Please remember this, and remember also that the processes of reproduction vary infinitely, and that when you look at a really beautiful production, full of harmonious light and shade, and delicate indications of graceful features where effect requires them, and exclaim "What a lovely map!" you may be merely the innocent victim of a skilful cartographer who has been backed up and perfected by a first-rate publisher.

I say this because it is undoubtedly the most effective and best-engraved maps which are accepted as the best. Indeed, I do not see that the public can judge in any other way, so the caution is really necessary. In maps especially it is not safe to judge too much by appearances.

It is interesting to observe the slow but gradual development of the art of topography from the earliest maps until now. The alphabet of the process (as I have already observed) has remained much the same. Mountains and plains, rivers and coast-lines, have been simplified and perfected so as to produce the most readable map, but the alphabet has not fundamentally altered. It is in the matter of relief chiefly that the change is noticeable. The earliest attempts at depicting mountains by pictorial elevation have given place to plan. The little groups of conical excrescences, like bands of haycocks, were by no means unintelligible, though purely conventional. Indeed, it may be doubted whether to some intelligences they are not even now a more effective illustration of hilly country than our latest and most scientific system of contouring. Between the two we may find every variety of method employed which can produce the effect required. In large scale maps dealing with comparatively small areas, and involving no great differentiation in altitude, such as rolling plains and subsidiary hills, it has long been decided that the only scientific method of depicting the country is by lines of contours (*i.e.*, lines of equal level) at definite vertical intervals. It undoubtedly has its drawbacks. There may even be a difficulty here and there in distinguishing between an elevation or a depression unless the value of the contours above the datum are distinctly stated in figures. But it is beyond dispute that for all military or fiscal purposes the contoured map is the only one admissible.

Difficulties arise when the elevations on the face of the map rise from the status of hills to that of mountains, and with the gradual steepening of slopes the delineation of contours gets closer and closer until it is impossible to introduce them on small scale maps without overlap and confusion. This applies to the many forms of geographical maps from the scale of one inch to the mile downwards, when it usually happens that some more artificial and less conventional method of illustrating mountains in plan is necessary. The difficulty is usually met by "hachuring"—that is to say, by introducing broken instead of continuous contours, and abandoning regularity of vertical interval. It is here that the artist steps in. He can cleverly introduce the effect of various shades of steepness within the limits of the steepest slopes in the map and the flattest, and give all the effect required to represent the wonderful complexity of a mountain system without committing himself to rigid lines of altitude if he has complete command of his pen and the perfectly trained eye of the true topographer for variation in hill conformation.

And if this is done with the original map of Nature spread out before him, if from some commanding eminence he can watch the play of light and shade over a rich and varied landscape, with its cunning indications of the lines of drainage (always the first to ask attention), its admirable modelling of areas which the Great Architect has moulded to the forms required by the tectonic influences of the earth's formation, here piled in the agonies of a violent upheaval there gently smoothed out with the action of wind and weather to the likeness of ripples left by the sea on its sands, or maybe uplifted to the skies in steps of broken crag and wild storm-split cliff; is it possible, I ask, for any cartographer sitting down in his chair within the four walls of an office-room to attempt a fair record of Nature's truth from rough indications brought to him by others, or to compile from a notebook a map equalling that which has been artistically written direct from the face of Nature? I have had to deal with topographers of many sorts, good and bad. I have had men who could almost indicate geological structure by topographical drawing, men who could from one or two vantage points cover an enormous area of country within the range of vision with hardly a perceptible error in distance, and a conception of what must exist in certain spaces into which they could *not* look which was almost weird. There have been men, too (natives usually), who, wandering over wide spaces of new country hitherto unexplored and unmapped, where Nature's features are often large and easily recognisable, where there is little or no complexity of artificial additions to the landscape due to human agency, where the fording of great rivers and the passage over great mountains is, perhaps, the chief feature of interest—in short, where the main object is to discover the best routes and to give a fairly accurate representation of mountain, plain, and perhaps desert on a small scale, who would in the short space of a few months cover an area of as much as 40,000 or 50,000 square miles, so

rapid and effective is the process of geographical map-making by a skilful and artistic plane-tabler with a few well-fixed points to work upon.

Do not imagine that this is mere hasty sketching, either. Here, again, the trained artist comes in. He will know at once what features are important in a military reconnaissance, and he will take care of them. A man to do this sort of work well must be no slave to conventional ideas. and he must, in addition to the artistic faculty, possess unbounded energy, pluck, and discretion. Of course, such men are rare, and it is only by a long and careful process of selection of the fittest that of all the men chosen in the first instance from native centres of education in India, or from the ranks of the Army, those who promise best are given their chance. It takes many years to make a topographical artist, just as it takes many years to make artists of other and better-known descriptions. Thank Heaven, we are getting them in the British Army at last! There is admirable work done by British military topographers in Africa, if not in the Colonies. The pity of it is that these original works of art never see the light.

The weakest link in that chain of processes which is the basis of scientific map-making, lies in the process of combining new work with old. Owing to the obvious necessity for publishing maps in sheets, it is impossible to secure perfect homogeneity in the matter of accuracy within such definite limits as the sheet imposes. Even in the best maps, let us say the Ordnance one inch per mile sheets, which have been perfected by years of careful surveying at the cost of great expense, we cannot be sure that the up-to-dateness of the map is absolutely equal in all parts of it. Indeed, we may be much more sure that it is not. People ignorant of the processes of map-making can have little idea how much the process of revision enters into the matter. The rapidity with which fresh artificial geography in the shape of roads, railways, houses, etc., springs into existence, combined with the action of wind and weather in changing the face of Nature, taxes all the resources of the Ordnance Survey to cope with it. And it is almost impossible to maintain a high standard of up-to-date mapping which is applicable to any one map in a sheet of any size all over the face of it. But when we come to the class of mapping which we include under the term geographical, *i.e.*, wide areas depicted topographically on small scales within the rigid lines of a restricted sheet, these variations in quality of accuracy become far more pronounced and more important. No one but the compiler (who keeps the record) can possibly say what is the exact value of any one portion of the map, how far it is to be trusted in the business of conducting military affairs or the international arrangements of boundary settlements.

A naive belief in the accuracy of a printed map compilation (which can only be compared to the faith of a child that everything must be true that is to be found in print) has foundered many a high political programme, even when the geographical features which may form the basis for a treaty have been correctly shown as they existed at the time the map was made. The face of the earth changes and locally changes very fast. Slight errors which we find in dealing with Ordnance Survey maps we find exaggerated tenfold in our geographical maps of Asia, Africa, or America.

We will take, for example, the geographical mapping of those far countries with which I am best acquainted, and for which mapping I have been partly responsible — let us say, the maps of the northern borderlands of India, of Afghanistan, Baluchistan, and Persia, with parts of North-East Africa and South America. In the compilation of those maps every class of work has been utilised, good, bad, and indifferent, and it has been obviously impossible to show on the face of the finished and printed map to what category any particular portion is to be referred. The artistic beauty of some of the originals is blurred and ill-treated by the process of publication. The elementary character of others has been disguised by efforts of imagination, and the level value of the printing process is accepted as representing a level value of general accuracy. It may be accepted, as a rule, that the most trustworthy part of the map is that furnished by the professional surveyor and explorer, and such work is generally easily recognised by the expert, though not so by the public. Then follows in value an infinite variety of the amateur efforts of travellers (I am quite aware that many of them would resent the term "amateur," but in my opinion the gap is not to be bridged which separates the two classes), and it is by no means the latest traveller's work that always proves the most trustworthy. We are all of us acquainted with the general style of the explorer's map of half a century ago, the long zigzag line representing his route, the occasional bearings recorded to distant peaks, the small wriggles indicating the rivers crossed, and possibly an arrow to show the direction in which they flowed, and beyond this a broad sheet

of unspoiled white paper. That is no longer the style of the plane-tabling explorer, who sketches all that he sees, who gets to every commanding eminence he can reach, and will spend days in reaching a point that would have been passed as insignificant in earlier times.

And yet all honour to those past pioneers in the work of geographical surveying, for with infinitely inferior means at their disposal and inferior education, they often made up by persistent steady effort, painstaking accuracy in what they recorded, and an almost weird capacity for all-round observation, for the want of scientific means for square surveying. I have in mind the work of some of the officers employed during the Afghan Campaign of 1838–42. It was restricted and narrow in the output, but so infinitely careful in detail that it was a pleasure to go through it all again and to realise by the light of present knowledge what it must have cost them in anxiety and labour to achieve such work. It is by the light of this earlier work that one realises how the geographical face of Asiatic lands can alter in a few generations. Where roads are but tracks they may shift their position almost indefinitely to suit new passes or fords, new centres of trade to be tapped, new villages sprung up with the extension of cultivation. As for the rivers of India, unless confined within rocky beds, their notorious irresponsibility in finding new channels and shifting their channels, drying up altogether here and breaking out with new springs there, is a perpetual source of anxiety to the engineer and of litigation to the landowner.

It is the same all over the uncivilised world. The eccentricity of river action nearly led to disaster in South America, and the same difficulty will give us trouble in Africa without doubt. No need to elaborate this propensity of our earth world to change its face, or of its more primitive inhabitants to change their habitations and call them perpetually by new names. I only refer to it as a caution to map critics.

I have said a word or two indicating that the gift of imagination must still have its place in map-making. This may sound almost immoral, although it is but a page from past records, and yet I have come to the conclusion that if the public is asked to exercise imagination in reading the map, the map-maker must meet the public half-way. It is still, of course, in the domain of geographical mapping where the conformation of the ground is partly well known, partly indifferently known, and partly conjectural, and where the process of map reproduction renders it exceedingly difficult to distinguish between these relative areas, that imagination must here and there be called upon to supplement actual knowledge. In the ordinary business of rapid geographical map-making in the field, the map-maker would prove himself to be but a sorry performer if he wasted valuable time (and time is almost always restricted) over features which could be of no practical importance whatever, whilst he neglected matters that were significant, either from the commercial, military, or political point of view. Or it might happen that whilst money is forthcoming to support the surveying of the infinite complications of mountain formation where that formation includes cultivated valleys or possible routes leading across passes to more important fields beyond, there is no warrant for expenditure over the wide stretches of snow-field and curving glaciers, the ice-ribbed cliffs and crags that lead up in shining steps to the thrones of the gods on the snow-clad peaks. And thus it happens that if the map-maker were to confine himself to absolutely what he knew to be true in the delineation of mountain and valley, or of rough desert areas wherein no living creature moved, he would simply leave large white blanks in his map which might in themselves be most misleading.

It used to be the fashion to leave such blanks, but in my opinion it is better to introduce mountains or deserts where they are known to exist, to indicate all that can be seen from a distance, to trace out from afar the probable origin of glaciers and mountain torrents, or to show by conventional forms the trend of the wind-blown sand-hills, than to make no sign at all. The part of the map which is conjectural should, of course, be carefully indicated; but there is doubtless a tendency on the part of enthusiastic explorers to consider much of these conjectures as certainty, and to make no specific distinctions between what they know and what they think they know. In this way it often happens that succeeding explorers in the same region are apt to condemn the work of their predecessors from want of knowledge of the exact nature of the different parts of that work. It is not enough in these days that an explorer should have previous map information of the region of his researches if he is not also exactly informed as to the accuracy and trustworthiness of every part of such map. I may say just a word here about map criticism. It is a most common thing for even intelligent travellers

passing over a country with a map in their hands to report that they found the map all wrong. Indeed, it is almost invariably the case. Now, in the case of expeditions into partially known lands, it is only the expert who can say whether the criticism is a just one or not. In most cases it is not, for the simple reason that ordinary travellers have no means of identifying their position, and do not know exactly where they stand; whilst, as regards place names, although they may succeed in identifying the position named, they are at the mercy of native guides and interpreters for their own information. In most cases the new view of the proper name for a village, a mountain, or a river, has no better foundation than the old one, probably not so good.

This, however, is beyond the usual experience of the British tourist in England. He will take, say, one of Bartholomew's half-inch maps in his hand, and still he will blunder hopelessly as to his exact position if he is travelling at any speed, and yet he will be equally certain that the map is wrong. I have already explained that there are bound to be weak spots in every guide map of this sort—some of them due to the processes of printing and reproduction, some due to want of revision, and the tourist may likely enough hit on one of them; but in the great majority of cases I have noticed that the criticism comes from want of identification of exact position. Even in the matter of that identification the traveller has only the map he is criticising to help him. He is not an expert surveyor with instruments and knowledge enough to render him independent of the map.

From what I have said you will gather, no doubt, that whilst professional map-makers are often hampered and sometimes misled by the results of the amateur explorer's observations, they are infinitely indebted to the few who will carefully make themselves acquainted with previous records touching the country they explore, and taking all the data they can get from professional sources, and a proper instrumental equipment, will endeavour to supplement geographical work in those remote regions which are partially known and conjecturally mapped.

I should like to say a word in conclusion about improving, if that is possible, the usefulness of the guide maps that are in everyone's hands in these days. There is one matter about which experts disagree more or less, and it is one on which I think the public might well express an opinion. It is the fashion now to indicate successive planes of elevation by flat tints, and the ordinary application of colour for that purpose is in shades of green for the lower elevations, rising into brown which deepens with the altitude. So well known is this system that I think it may be considered to have established a fair claim to permanence, so far as British maps are concerned. For my own part, I can imagine nothing better for ordinary touring maps. But difficulty arises when the altitudes are great, rising to many thousands of feet as in mountainous regions. Here it is admitted that no one universal system of colour-printing is satisfactory. This is not an unimportant matter, for it directly affects geographical education, which now is so largely assisted in schools by wall maps. In the effective preparation of these we want the opinion both of teachers and of artists. I have seen school maps where the mountains are depicted in bands of fiery red, which may certainly be effective in catching the eye of a pupil, but which, being quite apart from and beyond any scheme of Nature's colouring, are to me more distracting to the eye than persuasive to the mind. The impression of climbing up a red-hot staircase to meet the cooling influences of snow at the top does not seem in harmony with the general fitness of Nature's schemes. It is, indeed, in the hope of attracting more public attention to one of the utilitarian branches of an art that is not generally attractive that I have ventured upon offering these few words about maps to the Royal Society of Arts in the opening address of the session.

After delivering the Address, the Chairman presented the Society's medals, which were awarded for papers read during last Session.

At the Ordinary Meetings:—

P. Chalmers Mitchell, M.A., D.Sc., F.R.S., Secretary to the Zoological Society of London, "Zoological Gardens."

John Charles Umney, F.C.S., "Perfumery."

Arthur Fell, M.P., "The Channel Tunnel."

W. S. Rogers, "The Modern Poster: its Essentials and Significance."

Edward F. Strange, R.E. (Hon.), "Japanese Colour-prints."

William Reginald Ormandy, D.Sc., F.C.S., M.I.Automobile Eng., "Motor Fuels, with special reference to Alcohol."

R. A. Peddie, "The History of Colour Printing."

E. Halford Ross, M.R.C.S., "House-flies and Disease."

John Clarke Hawkshaw, M.A., M.Inst.C.E., "The Early History of the Channel Tunnel."

In the Indian Section:—

COLONEL T. HOLBEIN HENDLEY, C.I.E., "Indian Museums: a Centenary Retrospect."

MRS. PATRICK VILLIERS-STUART, "Indian Water Gardens."

GEORGE C. BUCHANAN, C.I.E., M.Inst.C.E., Chairman of the Rangoon Port Trust, "The Port and City of Rangoon."

SIR JAMES M. DOUIE, K.C.S.I., "The Punjab Canal Colonies."

In the Colonial Section:—

SIR ROBERT WILLIAM PERKS, Bart., Assoc.Inst. C.E., "The Montreal, Ottawa, and Georgian Bay Canal."

SIR BOVERTON REDWOOD, Bart., D.Sc., F.R.S.E., before proposing a hearty vote of thanks to the Chairman for his excellent address, said he desired to say that it was very satisfactory to find the venerable Royal Society of Arts pursuing the even tenor of its way under the conditions which existed at the present time. It was true that the Press Bureau, with paternal solicitude for the mental well-being of the people of the country, administered to them war news in homœopathic doses; nevertheless the newspapers, morning and evening, were largely filled with particulars of engagements at the various points at which warlike operations were proceeding, and it was scarcely possible, therefore, for anyone to avoid assimilating a good deal more of that sort of information than was good for his nervous organisation. He ventured to say that there was no better sedative for overwrought nerves than to take an active part in the work of such a Society as that in connection with which the present meeting was being held. He had had the advantage of listening to many addresses from previous Chairmen of the Council, but he had never listened to a better one than that which had just been delivered. Some people professed to be able to get a good deal of enjoyment out of the study of the pages of "Bradshaw's Railway Guide." That was an exceptional or acquired taste, but there were very few people who had not an inborn love of maps, and it must therefore have been of the greatest interest to those who had been fortunate enough to hear the address read to learn the process of evolution through which the art of map-making had passed until it had reached its present state of perfection. There was, admittedly, no one better qualified to deal authoritatively with the subject than the Chairman, and very few who could have invested it with the charm with which it had been presented. He was, therefore, sure he expressed the sentiments of all present when he proposed that a very cordial vote of thanks be accorded to the Chairman for his most interesting address.

THE RIGHT HON. SIR MORTIMER DURAND, G.C.M.G., K.C.S.I., K.C.I.E., in seconding the motion, said he had listened to the address with something more than pleasure, because the Chairman was a man who knew how to do things and how to write about them afterwards a very rare combination. Everything he wrote was clear, eloquent and comprehensive. Nevertheless, the chief impression left on his mind by the address was a painful one. He had always had the most simple and touching faith in the modern map, but Sir Thomas had shaken that faith very sadly. He remembered some twenty-five years ago, during the conduct of some negotiations with the Amir of Afghanistan, appealing to the maps in support of his contentions, but the Amir replied, "All your maps are wrong." The Amir proceeded to sketch on a sheet of foolscap, with a pencil that was blue at one end and red at the other, a map of his own which made one's brain whirl; but he (Sir Mortimer), after listening to Sir Thomas's address, was beginning to think that possibly the Amir had some reason on his side, because he was afraid that the Chairman was largely responsible for some of the maps that were impugned.

The vote of thanks having been carried by acclamation,

THE CHAIRMAN, after thanking the audience for the cordial way in which the resolution had been received, said he was particularly pleased to hear Sir Mortimer Durand's remarks, because he did not think there was a better judge of maps to be found anywhere in the country.

COTTON CULTIVATION IN UGANDA.*

Cotton is grown on all kinds of soils in Uganda. The black loams have been considered the most suitable, but the satisfactory growth of cotton is governed more by climate and season than by any nice distinctions in soils. Giving the black loams the preference where they occur, we may say that all the soils of the Protectorate are capable of producing good crops of cotton provided that the soil is in a condition favourable to plant-life.

As regards climate, there are districts which, on account of their elevation, are too cold for the satisfactory ripening of the crop, and others which are so dry that a sufficient rainfall is not to be depended upon. There is, however, a large area of the Protectorate which is eminently suited to the crop. In the first class of our cotton areas are the Teso and Lango districts, a great portion of the Bukedi and Busoga districts, the sazas of Bulemezi, Buruli, and Bugerere in Buganda Kingdom, and that part of Bunyoro which borders on the Nile. The crop may also be expected to give satisfactory returns throughout the greater part of Buganda.

* Issued by the Uganda Protectorate Department of Agriculture.

Variety.

Uganda cotton is the progeny of some American Upland seed imported into the country in 1910. The Department of Agriculture is constantly at work on the improvement of the staple, and issues the best seed available to cultivators. The whole seed supply is under the control of the Department of Agriculture, and only seed issued by or approved by the Department may be sown.

Selection of Soil and Site.

Having regard to what has already been said on the subject of soils, the selection should be governed by the usual considerations — that is, the best available should be chosen, and a waterlogged or thin stony soil avoided. The same remark applies to situation, which should not be more windswept than can be avoided.

It has been a common practice in Uganda to clear virgin land for cotton every season; this is quite unnecessary, and provided that the land has not been exhausted in any way, there are advantages in selecting land which has been cropped, as the soil can be put in a good state of cultivation with less trouble and expense. If groundnuts or beans are taken as the first crop on newly opened land, they make a good preparation for cotton.

Preparation of the Field.

The preliminary cultivations are of the utmost importance, and should be done thoroughly.

The land should be dug over or ploughed to a depth of 9 ins.; in the case of land which has already been cropped, the preliminary cultivation may be as deep as possible, but on virgin land it is not advisable to attempt to go deeper than 9 ins. In either case the land should be thoroughly cleaned, and all roots of grasses, etc., removed.

Time of Sowing.

The seasons in Uganda are so variable and local as regards rainfall, that no definite time can be fixed for the sowing. This is a matter on which each individual planter must use his judgment. The general sowing season extends from April to July, according to the occurrence of rain.

Among the natives of the Teso district the Department has introduced a system of double sowings. Each native cultivator has two plots, one of which he sows in April or May and the other in June or July, thus ensuring that at least one of his plots adapts itself to the vagaries of the season. In a favourable year both of his plots may do well, and he profits accordingly.

Distance of Sowing.

Cotton is sown in rows. There is no hard and fast rule as to distances, and these may be varied according to the capabilities of the soil. It has been found by trials that a distance of 4 ft. between the rows and 1 ft. 6 ins. between the plants in the rows is, on the average, the most suitable distance, and this has been adopted as the standard for native cultivators.

Method of Sowing.

The seeds are dibbled by hand at a depth of about one inch. It is customary to sow several seeds to each hole; this ensures a good stand of plants throughout the field, and the superfluous plants are pulled up later, one plant being left to each hole. The ratio of germination is invariably high, and an allowance of three seeds per hole will be found ample.

As soon as the young seedlings appear above ground any blanks should be re-sown.

In some countries cotton is sown on ridges. No advantage has been found in this system, and the universal practice in Uganda is to sow on the flat.

Singling.

The singling should be done when the plants are about 6 ins. high and have five or six leaves. The labourers should be instructed not merely to leave one plant out of each clump, but to leave the best plant of the clump.

It is better to make two operations of the singling; the first time the labourers should leave two plants standing, and a fortnight or so later the field may be singled. This process entails a little more work but ensures a good stand.

Cultivations.

The number of times that the field must be cultivated will depend partly on the season and largely on the thoroughness of the initial cultivation.

The field should be hoed over at the time of singling; the number of subsequent cultivations will vary considerably. The field must be kept clean, but it should not be forgotten that there are other objects in cultivation besides the eradication of weeds. It should be the object of the grower to maintain a good mulch—that is, to keep the top two inches of the soil well stirred and in a good condition. More especially is this of importance during dry weather, and, if the field is cultivated at the end of the rains, the resulting mulch will be of great assistance to the plants during the dry spell. It must be remembered that whereas the original cultivations before sowing should be as deep as possible, all subsequent cultivation should consist merely of surface hoeing.

Picking.

Picking will commence about five months after sowing, and the picking season will extend over several months, the number of pickings varying with the weather conditions experienced. The pickers should be provided with bags with two pockets, so that the clean and dirty cotton may be kept separate. They should be taught to seize the boll with one hand and take out all the cotton with one motion of the other hand, otherwise they will pick each lock separately and so waste time. After picking, the cotton should be put out in the sun for a day to ensure its being quite dry before it is stored.

DISEASES AND PESTS.

The cotton plant is subject to a large number of diseases and insect pests. A variety of these ills will be found in any cotton-field during most seasons, but it is only occasionally that any particular pest becomes a serious menace to the crop.

The best precaution against such of these diseases as are physiological or of fungoid or bacteriological origin lies in good farming. Damage caused by insects may be materially reduced by attacking the early generations, many of which can be hand-picked and their multiplication thus hindered.

THE FOOD VALUE OF ACORNS, HORSE CHESTNUTS, AND BEECH MAST.*

Acorns, horse chestnuts, and beech mast may all be used as food for stock if fed with discrimination, though there is evidence to show that if carelessly fed the results in the case of acorns and beech mast may be serious. Relatively, however, serious accidents are so few that there is no reason for avoiding these foods in times of scarcity, and the Board feel that at the present time full use might be made of them, subject to their being unaltered by moulds or ferments, and to their being given only in small quantities in conjunction with other foodstuffs.

Owners and occupiers of land who do not themselves have these products collected would probably gladly allow cottagers and others to gather them for their own use.

ACORNS.

It is an old-established custom in Great Britain to collect acorns for pig-feeding, or to turn out cattle and pigs to gather up the fallen fruits. Centuries ago, when fewer varieties of crops were grown, the rural population found the yearly yield of acorns of great value for feeding their pigs. In some parts of the country it is still the custom to collect acorns for the pigs, for feeding which they are commonly valued at about 1*s.* per bushel, though their real food value is probably much higher.

During the last thirty or forty years, however, there has apparently been a growing reluctance to utilise acorns to the extent which formerly prevailed, and this may be in part due to the fact that large numbers of cattle under three years old have been lost owing to the so-called "acorn poisoning."

There is some risk of injurious effects from the consumption of large quantities of acorns by young cattle, though not apparently by cattle over three years old, sheep and pigs. The "poisoning" does not usually follow on the consumption of acorns in small quantities, but is commonly due to full meals of acorns without adequate supplies of water in periods when there is a dearth of herbage. The evidence shows that when acorns, in sound condition, are given judiciously, in small quantities only, they are unlikely to cause any ill-effects, but are a valuable addition to the ration, more particularly in the case of pigs, but also for sheep and adult cattle.

The food value of acorns lies chiefly in the large quantities of digestible carbohydrates which they contain. On this account they would form a useful supplementary food to green fodder, and to such foods as are rich in protein, and they could, to a certain extent, replace in the ration cereal and other foods rich in carbohydrates.

Fresh acorns should preferably be fed only to pigs, sheep, goats, and adult cattle in moderate quantities, along with other foods, and the change to the ration containing acorns should be effected gradually. It is not safe to feed fresh acorns in any considerable quantity to pregnant sows, dairy cows, or young cattle. Where pigs are driven into woods they must be given green or other supplementary food which will supply a sufficiency of phosphates and lime, necessary substances which are present in acorns in only small quantities. Special care must be taken to withhold cattle from pastures where unripe acorns have been blown down.

Drying the acorns improves the flavour and feeding value and reduces the risk of illness, and acorn meal, prepared by grinding the kernels after drying and then separating them from the cracked husk by sifting after roughly crushing, has a feeding value approximately equal to that of barley meal and oat meal. Care should be taken not to feed any mouldy acorns.

NOTE.—The following are the symptoms of "acorn poisoning," which, as has been explained, affects young cattle almost exclusively:—Progressive wasting, entire loss of appetite, diarrhœa (which may sometimes be tinged with blood), discharge of an excessive quantity of pale urine, sore places inside the mouth, discharge from the nostrils, and also from the eyes, which are always sunken, giving the animal a peculiar haggard expression. No fever is present from first to last, but, on the contrary, the temperature is commonly below the normal standard, though in some cases stated to be above the normal.

HORSE CHESTNUTS.

The quantity of horse chestnuts that may be fed to animals need not be limited from considerations as to any poisonous effects, as they do not appear to be poisonous.

The following quantities of fresh and unprepared nuts have been fed per head per day:—½ to 1 lb. to sheep, or up to 2 lbs. to fattening sheep; 4 to 10 lbs. to dairy cattle; about 12 lbs. to working oxen; and about 6 lbs. to horses. They may be fed whole, but should preferably be crushed; they should on no account be fed unprepared if they are mouldy. It is doubtful whether pigs can be induced to eat them unprepared, but in the form of meal pigs have been given up to 1¼ lb. with good results.

* Special Leaflet No. 9, issued by the Board of Agriculture and Fisheries.

Wherever practicable, and especially where it is intended to feed quantities of chestnuts to stock, chestnut meal should be prepared from the kernels after removing the husk. The nuts can be dried in a hop oast by using a good fire, or in any oven in which the temperature can be raised to about 160° F. After drying and partial crushing the greater portion of the outer husks may readily be removed and the residue ground to a meal of any desired fineness. Auld remarks that to obtain a meal of better flavour, to which animals can be sooner accustomed, the nuts, after drying and partial crushing, may be allowed to soak in cold water overnight, after which they are boiled for half an hour or so; the water is then rejected, and the residue is dried, partially husked, and reduced to a meal as before. Horse chestnut meal prepared in some such way would be a fairly concentrated food, and would prove very useful for fattening purposes or for store cattle once the animals can be accustomed to the food. Based on a comparison of starch equivalent 1 lb. of horse chestnut meal would be equal to 1 lb. 1 oz. of feeding barley, or 1 lb. 4 ozs. of oats, or 1 lb. 8 ozs. of bran, or 2 lbs. 5 ozs. of good meadow hay.

Both the whole chestnuts and the meal are chiefly valuable on account of their content of digestible carbohydrates. They would form a suitable supplementary food to watery foods, *e.g.*, green fodder, silage, root leaves, or beet pulp, and they would also be useful when feeding damp food or green food wet with rain. On the other hand, chestnuts are somewhat astringent, and if taken in large quantities unaccompanied by watery foods have been known to cause digestive disturbances, particularly stoppage. The addition of salt not only prevents this, but has the effect of making the ration more tasty. Oil cakes rich in protein, hay, and straw seem suitable complementary foods in addition to the watery foods mentioned above. Owing to their high total digestibility, chestnuts would probably increase the total digestibility of a ration in which they are fed as a supplementary food. Where animals cannot at first be induced to eat the nuts or meal, a little treacle may be added to mask the bitter taste.

BEECH MAST.

Comparatively little seems to be known as to the value of beech mast as a feeding stuff, and no exact experiments appear to have been carried out with it. It may be said, however, that beech mast should not be fed to horses, which are susceptible to a deleterious constituent of the mast, and that sheep will either not eat the mast at all, or can only be made to do so under compulsion. Further, the husk contains so high a percentage of crude fibre that the whole mast is unsuitable for feeding purposes, and only the kernel should be fed. A fine oil is obtained from the kernel, and hence the question of feeding the residues (or cake) might arise.

The shelled kernels and shelled cake are rich in albuminoids but have a low content of carbohydrates, so that suitable complementary foods would be those poor in protein but rich in carbohydrates. The small quantities of tannin present are negligible from the feeder's point of view.

Beech mast has been fed to cattle and pigs without harm, and it is stated that cattle are not susceptible to the constituent which has been found harmful to horses. Poultry, especially turkeys, readily eat beech mast, on which they fatten quickly.

Beech mast which has become damp or slightly mouldy should be cooked before feeding. Plenty of drinking water should be allowed to the animals.

THE HYDRAULIC MINING CARTRIDGE.

In the course of a paper on "The Uses of the Hydraulic Mining Cartridge," read before the Society of Engineers (Incorporated) on November 2nd, Mr. James Tonge stated that the disadvantage and danger of employing explosives to excavate rock and other material from confined places had long been recognised. The effect of blasting could not always be confined to the area desired to be dislodged, and the use of explosives must involve either the risk of accident through insufficient charge or the production of misapplied energy.

Many mechanical substitutes for blasting had been devised to avoid these drawbacks, the simplest form being the wedge. The stub and feather and the multiple wedge had been used as improvements on the simple wedge; and in coal mines wedges invented by Bidder, Burnett, Shreeve, and Hall had been employed. These all had proved impracticable, and, except in the case of the simple wedges, were now practically out of use. The hydraulic mining cartridge was not worked on the principle of a wedge. It consisted of a steel cylinder containing a number of telescopic pistons operating at right angles, which expanded upon the application of water from a hand hydraulic pump attached to the cylinder by a steel pipe. The cylinder was placed in a suitably drilled hole, and the rock removed gently.

As the operation proceeded it was possible to see the rock slowly fracturing, and at the conclusion of the operation the débris were left in good condition suitable for speedy removal. Explosives could not be made to take advantage of the natural bedding and cleavage of rocks, their violence being expended on "hacking through" to the nearest unsupported edge. With the hydraulic cartridge it was possible to excavate greater areas at one operation, the weight of the detaching strata itself being used to increase the scope of the operation.

The hydraulic cartridge was used to a large extent in mines for (*a*) commercial reasons; (*b*) safety. The machine had been found equally applicable to work either in open trenches or under water. In considering the excavation of concrete beds by a method which would not involve

explosive blasts, it was necessary to remember that there was a wide difference between concrete and stratified deposits. In the latter case there was only slight crushing of the rock before the applied pressure caused the mass to bend and crack; whereas in concrete considerable pumping had to be employed without any apparent effect before the fracture appeared. This was due to the crushing or compressing that the mass would withstand before finally breaking. Further pressure, of course, increased the magnitude of the break.

It was found that concrete foundations were particularly well suited to the application of this machine, horizontal and vertical shots being arranged at intervals all round the bed and pumped off in turn. About 3½ tons of material could be excavated per thrust.

PIEDMONT: ITS AGRICULTURE AND INDUSTRIES.

Major Percy Chapman, who is now Consul-General at Turin instead of Florence, where he was formerly quartered, has signalised his new appointment by writing an interesting report on the agriculture and industries of Piedmont for 1913. The entire region consists of plains, which occupy one-fourth of the whole area, 6½ million acres of which are under cultivation. The highest regions of the Alps consist, of course, of glaciers and rocks, below which are pastures, first bare, afterwards shrubbed by rhododendrons, and then by larch, fir, and pine woods, and lower down by beech, chestnut, and oak woods, intermixed with lime, maple, ash, birch, cherry, willow, alder, acacias, and elm trees. Unfortunately most of the luxuriant woods which are said to have once existed on the Alpine and Apennine slopes have been despoiled of their best trees without any regard for re-afforestation. The Piedmontese plain consists to a great extent of Alpine diluvial soil, which in the more elevated regions presents itself to the tiller in a denuded state, while in the lower zones it is covered by alluvial strata carried down by numerous rivers.

As far as regards emigration, the last statistics are those for 1911, when the total number of Piedmontese who emigrated abroad was 52,365, the greater part to various European countries and those bordering on the Mediterranean.

During the last twenty years remarkable progress has been observable in all branches of agriculture, the consumption of fertilisers having greatly developed, and the use of agricultural machinery being now met with particular favour. The imports of the latter were valued in 1904 at £248,620, while in 1913 the same item had risen to £759,103. Modern methods of culture and rotation of crops are being generally adopted, with the result that the production of cereals and forage has more than doubled, and land has increased in price by about 25 per cent., and in some communes by over 40 per cent. Government experimental farms, agricultural associations, agrarian boards, and particularly ambulatory schools (*Cattedre Ambulanti*), through their exertions and teachings, have helped materially to bring about the increased production. But still much remains to be done. Live-stock breeds require improvement, silviculture is not sufficiently cared for, pastures might give much larger yields, fruit-growing is capable of further improvement, and scientific poultry breeding is almost unknown.

With regard to exports, Turin is an important market for wines, especially Barolo, Asti, and the popular vermouth. Cuneo is the largest market in the world for cocoons, and the best in Italy for chestnuts. The Vercellese district and Novarese plain form a centre for rice-growing which extends over 617,500 acres. Irrigation is much developed throughout all Piedmont, and more especially in the Province of Novara, Turin, and Alessandria, and on the hills of the Province of Cuneo, where canals belonging to the State have been in existence from olden times. The largest canal is the Canale Cavour, measuring fifty miles in length and irrigating an area of about 750,000 acres. Vine-growing has in Piedmont considerable importance, the area under vines being 719,511 acres, while the Province of Alessandria ranks as the finest wine-producing district among all the provinces of Italy. Among the miscellaneous rural products may be mentioned the white truffle of Piedmont (*Tuber magnatum*), which is said to enjoy exceptional renown both for flavour and perfume. It is stated that Napoleon I. and Rossini preferred it to any other. In times of scarcity the Piedmontese white truffles reach the extravagant price of 60 lire (£2 8*s*. per kilo.). The white truffle is found in close proximity to the roots of the oak, willow trees, and poplar, but never beyond 1,640 feet above sea-level. The search is made by means of dogs, chiefly water-spaniels, or pigs. In Italy, truffles as well as mushrooms are considered a free produce of the soil and belong to the finder. Another characteristic product is that of vermouth, the origin of which is very ancient, being mentioned as far back as the time of Cicero. It was manufactured in Tuscan farmhouses as early as the beginning of the eighteenth century, and was even then known by the name of vermouth. It was probably imported from Tuscany in 1786 into Piedmont, where it gradually became known and appreciated, and large factories were started, some of which at present cover very extensive grounds, and possess numerous storehouses and vaults.

BASKETS USED BY GERMAN ARTILLERY.

The American Consul-General at Coburg states that his attention has been directed to a new feature of the basket industry at Coburg. This is a full line of baskets made in various sizes and shapes for the army, and used in transporting shells and

cartridges. The largest-sized baskets are made to contain one shell each, such being used for coast artillery. Other baskets are made in various shapes, with receptacles for shells and cartridges. All the latest patterns of baskets for transporting shells are made with eight strips of hard wood, four on the outside and four on the inside, extending from the top to the bottom of the basket. The outside strips are to protect and strengthen the basket, and the inside ones to keep the shell in place. Within these baskets are placed two strips of canvas belting, attached to a circular leather bottom upon which the shell rests. The outer ends of the strips are fastened together, making a sort of handle by which the shell is lifted from the basket, the bottom resting on the leather circle. Baskets are made in various sizes to suit the shells, and others with divisions to accommodate cartridges and explosives. The wood with which these are strengthened is very hard and tough, and is supplied by the Government. The baskets are manufactured in large quantities, and are kept filled with shells and cartridges at the artillery depots. During manœuvres, and in case of war, the baskets containing the shells are loaded on the railway trains and taken to the front for use. Through the use of the baskets the shells and explosives are protected from contact with hard substances. The baskets containing shells for field artillery stand upright in the gun-carriages. Within the last few years upwards of 1,500,000 baskets have been made for the German Army. Before the war large deliveries of baskets were made to Austria and Turkey.

ARTS AND CRAFTS.

Women's Work in Arts and Crafts.—It is, perhaps, inevitable in the general upheaval caused by the war that craftworkers as well as other people should try to increase their business by putting forward any plea that occurs to them. But, when all has been said, it is to be doubted whether the suggestion of the promoters of *The Englishwoman* Exhibition of British Arts and Handicrafts, to the effect that since British handicrafts have for many years suffered from the competition of machine-made articles from Germany there is now an unprecedented opportunity for the revival of our ancient and beautiful arts and crafts, has very much to commend it. To tell the truth, German competition of any kind has had but little influence on craftwork in this country. The real rivalry has been between British and German manufactures, and it is British trade and design, rather than craftsmanship, which may hope in the long run to benefit by the war. Our imports from Germany have not in the main belonged to those types of expensive machine-made goods which may be taken as competing seriously with handicraft. German goods with any artistic pretensions have generally been bought because they were cheap, not merely comparatively cheap, but cheaper than anything which was manufactured in this country. It is well that people should realise this fact, and not build hopes of a boom in craftwork on a very insecure foundation. On the other hand, it would be very much to be regretted if the general desire to economise, and to spend money mainly on objects directly connected with the war, should lead to stagnation in the many branches of artistic craftsmanship in which good work is being done.

The exhibits at Maddox Street reached, many of them, quite a good level of accomplishment. Most of the crafts practised by women were represented, and such seasonable objects as hand-written and illuminated Christmas cards and calendars, or hand-coloured prints and reproductions destined for the same purpose, were good of their kind. The greatest interest of the exhibition, however, lay in the textile exhibits. Women's exhibitions are, of course, usually strongest on this side, and *The Englishwoman* Exhibition was no exception to the rule. The rugs and woven fabrics were specially worthy of notice on account of their colour, which quite often was both unusual and good. Some of the shades produced by the Cullompton Weavers were specially fine, notably the orange, whilst good work was shown by the Somerset Weavers. Mrs. Mairet of Shottery, Stratford-on-Avon, exhibited some children's dresses, etc., into which patterned weaving was successfully introduced and made use of to very good purpose. There was some very satisfactory needlework in the traditional styles and stitches of the Eastern Mediterranean shown by Lady Egerton's Cretan School; the Friends of Armenia exhibited some interesting semi-Oriental work, and the British needlework was represented by specimens sent by Miss Nowall, the Fine Needlework Association, and others. What seemed to be a new departure on really admirable lines was the collection of designs from Old English, Persian, Turkish, Italian and other sources prepared by the Alphabet Transfer Company. There are many women who have neither the time nor the skill to make their own designs, and some of them are persons of taste who do not wish to waste their energies on reproducing with much labour just the ordinary trade transfer patterns. The designs put forward by the Alphabet Transfer Company (to be obtained from Miss S. I. Welsh, Owslebury House, near Winchester) are for the most part admirable, and marked by a real distinction. The company, moreover, has had the wisdom and the forethought to provide worked models to show how the patterns may be executed with good effect. This is a way of encouraging good design and workmanship which ought not only to prove a boon to many people, but to become a really educative force. It is to be hoped that the effort will meet with that success which it undoubtedly deserves.

Decoration and Wallpapers.—The European situation has made things very dull in the trades connected with house decoration. Here and there some enterprising firm makes a little show of

energy, and textiles and wallpapers in which lions or crowns or patriotic emblems of one sort or another form an important feature are ostentatiously displayed in the windows, but on the whole there is little of interest to be seen, and, oddly enough, the change of temper produced by the war has made some of the patterns and treatments which would only a few months ago have attracted most attention seem altogether out of place. Further, as regards wallpapers, many of the necessary materials are unavailable or the supply of them is restricted. Flock, for instance, comes from France, where the makers are at present otherwise engaged and have no leisure to produce it. Some of the paper itself is made abroad, and though Holland at any rate can go on producing her share of that, even then bringing it over to this country is not quite such a simple operation as it is in more normal times. As to the colours, bronzes, etc., the paper-stainers seem to be in much the same position as the textile printers, and to be suffering, or expecting to suffer, as the result of having relied to a very large extent on Continental manufacturers. In view of all these difficulties, added to the natural fear on the part of the manufacturers that people will be in no mood for spending their money on decoration, it would not have been surprising if no new patterns had been proceeded with for next season. Such a state of affairs would have pressed rather hardly on the designers, and upon just those designers who are practical men, and whose services will be of the greatest value when it comes to the capturing of trade after the war. It is, therefore, cheering to find that the preparation of next year's patterns in block-printed papers has gone on as usual, and that in no niggardly fashion. Messrs. Jeffery & Co., whose reputation rests so largely on their block-printed work, are bringing out a whole series of designs worthy of the best English traditions. They are producing patterns by Edgar Patterson, Sydney Hayward, Heywood Sumner, and other well-known designers, and as wide a range of designs as usual will be obtainable. Some are large damask patterns or rather smaller all-over designs on traditional lines, others are in the style which some particular artist has made his own, but what might be taken perhaps as the prevailing tendency of the season is rather towards naturalistic treatment. Some of the flower designs, in which the blossoms are massed together very much as they might be seen in a herbaceous border, look as though they would make excellent backgrounds and they afford opportunity for really beautiful colouring. The panel form of dividing up the wall is, of course, provided for, and the modern demand for a wallpaper which shall look like anything rather than what it really is has left its mark on some of the fillings and backgrounds. It is obvious that people who want really the last new thing in wallpapers next season will be able to have it and to have it of the best quality. Although block-printed wallpapers wear so well that they cannot be called an extravagance, they cannot compete in the matter of price with machine-made papers. To bring them out at a time like this is a venture of faith which, in the interests of artists and workers no less than of the manufacturers, is deserving of all possible support from the public.

CORRESPONDENCE.

BRITISH TRIMMINGS AND EMBROIDERY.

In connection with the article on trimmings and embroidery which appeared in the *Journal* of November 6th, the difficulty which strikes me is that of knowing what fashion will demand next. By the time trimmings of any special sort have appeared in shops or fashion papers it is too late to make designs for that particular kind of thing. Articles having been produced, it is the object of the manufacturer to sell them, and not to let any one suggest designs or colours which might possibly overshadow his. I should be very glad if any reader of the *Journal* could suggest a way out of this difficulty.

F. EDITH GILES, Principal.

Clapton and Stamford Hill School of Art,
81, Clapton Common, N.E.
November 16th, 1914.

GENERAL NOTES.

OPENINGS FOR SOAP IN THE RED SEA MARKET.—According to the American Consul at Aden, conditions there are favourable for the introduction of American soap. If that be the case, then there should be an opportunity for the British manufacturer to increase his trade, for it appears that out of 12,547 cwt. of soap imported into Aden in the year ended April 1st, 1913, only 409 cwt. came from the United Kingdom, France contributing to the extent of 90 per cent. of the total imports. Of the total quantity imported into Aden, 8,000 cwt. were sent to Hodeidah and Jeddah, 900 cwt. to Massowah and Italian East Africa, and 1,014 cwt. to the Arabian hinterland. The success of French soap is attributed to the fact that it was the first on the market, and that a large stock has always been kept on hand by the importers. In introducing soap to this market manufacturers must bear in mind that the great mass of the population are Moslems, and eschew any composition of foreign manufacture likely to contain animal fats. Only soap made from vegetable oils should be brought to this market, and each cake of soap should be stamped accordingly. As most of the natives are illiterate they are often influenced by the trade-mark, and if satisfied with the article it is difficult to persuade them to accept another mark. A trade-mark reproducing an animal should be carefully avoided. A palm tree or a rose, for example, would appeal to a native's taste and

memory, and do much towards inducing him to the belief that no animal matter is contained in the soap.

MARKET FOR CEMENT IN THE CANARY ISLANDS.—No cement is manufactured in the Canary Islands, but the consumption is larger than is usual in communities of like population. As the rainfall is slight, and agriculture depends upon irrigation, the whole cultivated country is dotted with water tanks and lined with aqueducts of concrete. New water sources are constantly being developed, extending the arable area, and the construction of new tanks and conduits, added to the considerable building activity in the cities and towns, creates a large demand for Portland cement. For many years the United Kingdom supplied more cement than any other country, but in 1911 Belgium took first place, and has since held it by increasing margins. There are six countries competing for the Canary Islands cement market, namely, Belgium, France, Germany, Netherlands, Spain and the United Kingdom, and the various makes of cement are better advertised in the Canary Islands than any other article of local consumption, newspapers, announcements on the walls, bill boards and cinematograph films being all used to obtain publicity. In connection with the question of imports of Belgian cement into the Canary Islands, it may be mentioned that this cement is labelled entirely in English, is usually without marks indicating its origin, and, like other Portland cements, comes in barrels of 180 kilos. (approximately 400 lbs.).

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 23...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. R. A Peddie, "The History and Practice of the Art of Printing" (Lecture I.)

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. A Yusuf Ali, "India's Rally round the Flag."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Mr. E. Savile, "Our Wheat Supply."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Viscount Bryce, "The Mental Training of a Traveller."

Faraday Society, at the Chemical Society, Burlington House, W., 8 p.m. 1. Introductory address by the President, Sir R. Hadfield, on "The Hardening of Metals." 2. Dr. G. T. Beilby, "Some Recent Papers on Hardening and Overstrain in Metals, and the bearing on these of the author's Amorphous Theory of the Hardened State." 3. Professor E. Cohen, "The Influence of Allotropy on the Metastability of Metals and its bearing on Chemistry, Physics, and Technics." 4. Paper by Professor H. C. H. Carpenter. 5. Paper by Professor J. O. Arnold. 6 Professor C. A. Edwards, "The Hardening of Metals by Quenching." 7. Paper by Dr. W. Rosenhain. 8. Mr. A. McCance, "The Interstrain Theory of Hardening." 9. Mr. J. C. W. Humfrey, "The Part Played by the Amorphous Phase in the Hardening of Steels." 10. Dr. C. H. Desch, (a) "The Hardness of Solid Solutions"; (b) "A Note on Twinnings and the Martensitic Structure." 11. Dr. T. M. Lowry and Mr. R. G. Parker, Note on "Metallic Filings." 12. Professor H. M. Howe and Mr. A. G. Levy, "The Hardening of Manganese Steel." 13. Mr. H. L. Heathcote will Demonstrate instruments for Testing Hardness.

Medicine, Royal Society of, 1, Wimpole-street, W. Section of Odontology, 8 p.m. 1. Presidential Inaugural Address. 2. Dr. H. L. Lack, "The Influence of Nasal Obstruction on Abnormalities of the Jaws."

TUESDAY, NOVEMBER 24...Photographic Society, 35, Russell-square, W.C., 8 p.m. Lantern Lecture.

Zoological Society, Regent's-park, N.W., 8.30 p.m. 1. Messrs. E. Heron-Allen and Arthur Earland, "Exhibition of Tests of Arenaceous Foraminifera to introduce a Discussion on the Interpretation of these Structures." 2. Mr. D. M. S. Watson, (a) "A New Fossil Reptile from South Africa"; (b) "Notes on some Carnivorous Therapsids"; (c) "*Eunotosaurus africanus* Seeley, and the Ancestry of the Chelonia." 3. Mr. F. A. Potts, "Polychæta from the N.E. Pacific: the Chætopteridæ. With an Account of the Phenomenon of Asexual Reproduction in *Phyllochætopterus* and the Description of Two New Species of Chætopteridæ from the Atlantic."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. H. A. Ellis, "The Expansion of Britain's Imperial Relations with the Oversea Dominions resulting from the War."

WEDNESDAY, NOVEMBER 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Sir W. A. Tilden, "The Supply of Chemicals to Great Britain and her Dependencies."

Literature, Royal Society of, 20, Hanover-square, W., 8.30 p.m. His Excellency Senhor Manoel Oliveira Lima, "The Influence of European Thought on Brazilian Literature."

THURSDAY, NOVEMBER 26...Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Camera Club, 17, John-street, Adelphi, W.C., 8 30 p.m. Mr. A. E. Johnstone, "Greek Days and Greek Ways."

Electrical Engineers, Institution of, Victoria-embankment, W C., 8 p.m. Mr. W. M. Selvey, "Power-plant Testing"

FRIDAY, NOVEMBER 27...Literature, Royal Society of, 20, Hanover square, W., 5 p.m. Meeting of the Academic Committee. The following Addresses of Reception will be delivered :—To Mrs. A. Meynell, by Mr. H. Newbolt; to Mr. G. L. Dickinson, by Mr. A. C. Benson. Mr. J. Masefield will make the fourth award of the Edmond de Polignac Prize.

Engineers, Junior Institution of, 39, Victoria-street, S.W., 8 p m. Mr. C. E. Ford, "A Model Drawing Office System."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Medicine, Royal Society of, 1, Wimpole-street, W. Section of Epidemiology and State Medicine, 8.30 p.m. 1. Dr. W. G. Armstrong, "The Recent Epidemic of Smallpox in New South Wales: Its Diagnosis and Prevention." 2. Drs. J. B. Cleland and E. W. Ferguson, "The Nature of the Recent Smallpox Epidemic in Australia."

SATURDAY, NOVEMBER 28 ... Chadwick Public Lectures, Bedford College, Regent's-park, N.W., 3 p.m. Dr. A. T. Nankivell, "Camp, Ship and Hospital Hygiene." (Lecture III.)

Municipal Engineers, Institution of, 4, Southampton-row, W.C., 11.45 a.m. Annual General Meeting. 2.45 p.m. 1. Presidential Address, by Mr. H. Boot. 2. Mr. G. B. Chilvers, "A Plea for the Better Remuneration of Municipal Surveyors and Inspectors of Nuisances in small Urban and Rural Districts." 3. Mr. E. Whitwell, "Housing of the Working Classes." 4. Mr. J. S. Wooddisse, "The Future Control and Maintenance of Rural Roads."

Journal of the Royal Society of Arts.

No. 3,236. VOL. LXIII.

FRIDAY, NOVEMBER 27, 1914.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK

MONDAY, NOVEMBER 30th, at 8 p.m. (Cantor Lecture.) R. A. PEDDIE, Librarian, St. Bride Foundation Typographical Library, "The History and Practice of the Art of Printing." (Lecture II.)

WEDNESDAY, DECEMBER 2nd, at 8 p.m. (Ordinary Meeting.) WILLIAM REGINALD ORMANDY, D.Sc., F.C.S., "Britain and Germany in Relation to the Chemical Trade." The RIGHT HON. LORD MOULTON, LL.D., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, November 23rd, MR. R. A. PEDDIE delivered the first lecture of his course on "The History and Practice of the Art of Printing."

The lectures will be published in the *Journal* during the Christmas recess.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Tuesday afternoon, the 24th inst. Present:—

Sir Steyning William Edgerley, K.C.V.O., C.I.E. (Chairman of the Committee), Sir Arundel T. Arundel, K.C.S.I., Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., Thomas Jewell Bennett, C.I.E., Sir M. M. Bhownaggree, K.C.I.E., William Coldstream, B.A., I.C.S. (retired), Laurence Currie, M.A., J.P., Right Hon. Sir Henry Mortimer Durand, G.C.M.G., K.C.S.I., K.C.I.E., James Fairbairn Finlay, C.S.I., I.C.S. (retired), R. A. Leslie Moore, I.C.S. (retired), Colonel Charles Edward Yate, C.S.I., C.M.G., M.P., with Sir Henry Trueman Wood, M.A. (Secretary of the Society), and S. Digby, C.I.E. (Secretary of the Section).

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 6th and 13th, 1915, at 5 p.m., by MR. H. PLUNKET GREENE, who gave a course of Cobb Lectures on "The Singing of Songs, Old and New" last session.

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 25th, 1914; SIR WILLIAM RAMSAY, K.C.B., LL.D., Sc.D., F.R.S., F.I.C., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bates, Onward, 332, South Michigan Avenue, Chicago, Illinois, U.S.A.

Bone, Philip James, New Bedford-road, Luton, Bedfordshire.

Fearnley, Ths., Messrs. Fearnley & Eger, Post Box 223, Christiania, Norway.

Otis, Herbert Foster, The Laboratory, Nahant, Massachusetts, U.S.A.

The paper read was—

THE SUPPLY OF CHEMICALS TO BRITAIN AND HER DEPENDENCIES.

By Sir William A. Tilden, D.Sc., LL.D., F.R.S.

To those who can look back over half a century, the progress of scientific and industrial chemistry, and the relations of the one to the other, present many features of extreme interest. After the days of Lavoisier, and during the earlier part of the nineteenth century, the foundations of theoretical chemistry were laid by the efforts, contemporaneous but independent, of the chemists of England, France, and Sweden. The great names associated with the movement include Davy, Faraday, Dalton, Gay-Lussac, Dumas, and Berzelius. There were no German chemists of the first rank in those days, and if we look among them for fundamental discoveries we can only find one of considerable importance, namely, the discovery of isomorphism by Eilhard Mitscherlich in 1819. But the birth of Justus Liebig at Darmstadt, in 1803, gave to German science a leader whose influence stretches down to our own day, and is felt wherever chemistry is studied or practised. The department of organic chemistry has been the field in which the most remarkable successes have been won, though not wholly, as sometimes represented, by the German chemist.

The relation of optical activity to atomic constitution was the discovery of Le Bel, a Frenchman, almost simultaneously with Van 't Hoff, a Dutchman, and the application of their theories to the phenomena presented by compounds other than those of carbon, was illustrated in the first instance by Smiles, and by Pope and Peachey, all of whom are Englishmen. It will also be only fair to state that while we readily acknowledge with admiration the brilliant work of Von Baeyer and Emil Fischer in connection with the synthesis of indigo, the sugars and the proteins, the fundamental principles which underly all chemical theory, have been established almost entirely by the chemists of other nations. It is only necessary to recall such subjects as the atomic theory, the periodic law, Faraday's laws of electrolysis, the theory of free ions, the phenomena of radioactivity, and the discovery of radium, to show that in laying down broad general principles German chemists have not usually been the first in the field, though at later stages they have shown great and commendable activity.

Turning now to the position of industrial chemistry, a single brief quotation from the "Report on Chemical and Pharmaceutical Products and Processes" in the International Exhibition of 1862, from the pen of A. W. Hofmann, then Professor of Chemistry in the Royal College of Chemistry and Royal School of Mines, London, will be sufficient. He says (p. 3): "The contributions of the United Kingdom, and in particular the splendid chemical display in the Eastern Annexe, prove the British not only to have maintained their pre-eminence among the chemical manufacturers of the world, but to have outdone their own admitted superiority on the corresponding occasion of 1851."

On referring to the table of statistics which appears on the same page of the report, we find that of the 762 exhibitors in the class, the United Kingdom was represented by 200, while Germany, Austria, the Zollverein and the Hanse towns together mustered only 136. France stood next with 115 exhibitors. It will be remembered that at the date of the exhibition, the discovery of the so-called aniline colours was bearing very important industrial fruit. Mauve, or aniline purple, was discovered by W. H. Perkin in 1856, and aniline red was first obtained industrially by Verguin and Renard frères of Lyons a few years later.

It is also interesting to notice that among the early investigators and patentees of processes connected with the production of colour from coal-tar hydrocarbons, only English and French names are to be found, with the significant exceptions of Hofmann and Caro, both of whom were at that period resident in England. At this time synthetical chemistry in the modern sense was as yet unpractised because unknown. Such an important substance as salicylic acid, for example, was a mere laboratory product, obtainable only from natural sources.

But the activity of the chemical industries in the United Kingdom is not to be measured only by reference to subjects such as those of the coal-tar colours, nor by the number of exhibitors in an international exhibition even at that early period in the history of exhibitions, at which manufacturers were far more eager to find a place than they have been in more recent times. Statistics in relation to the development of the alkali trade show how rapidly the production of what are called "heavy chemicals" was proceeding at this period. Figures derived from returns collected by Mr. Christian Allhusen from 81 per cent. of the manufacturers in the United Kingdom,

immediately after the first Great Exhibition, are shown below. These may be compared with statistics prepared by Mr. W. Gossage for the year 1861 immediately before the Exhibition of 1862 * :—

	1852.	1861.
	Tons.	Tons.
Soda Ash.	71,193	156,000
Soda Crystals . . .	61,044	104,000
Bicarbonate	5,762	13,000
Bleaching Powder .	13,100	20,000

The value of these products for 1852 was estimated at about 1¼ million pounds, while the value of the products of 1861 was calculated by Mr. Gossage at upwards of two millions sterling.

The Board of Trade has recently issued a Bulletin concerning German competition in the United Kingdom market, and on page 2 we find the statement that the soda compounds, excluding chromates and bleaching powder, produced in the United Kingdom in the year 1907, are valued at £3,390,000. The imports from Germany in 1912 are valued at only £8,700. As to bleaching materials, the product of the United Kingdom for 1907 is estimated at £527,000, while the import from Germany for 1912 was £44,600.

From these figures the easy deduction is made that " the imports of these chemicals into the United Kingdom from Germany are relatively insignificant when compared with the output of the same articles in this country. It is clear that in these particular lines British manufacturers have no need to fear German competition in the home market."

Similar remarks apply to aluminous compounds, coal-tar products not dyes, the cyanides, sulphuric acid, and other acids for which the Bulletin may be consulted. It thus appears that the British manufacturers of sulphuric acid and soda, from the early times of a century ago, have been able, up to the present, to hold their own against foreign competition, and have thus added substantially to the revenues and well-being of their country.

The immense advances in every direction made in all civilised countries have brought demands in steadily increasing quantities for a variety of materials of which many were unknown to the generations immediately preceding our own. These are almost all the outcome of the progress in our own time of chemical knowledge. Since the introduction of the coal-tar dyes the development of chemical theory has rendered possible the production in the laboratory of a large number of organic substances which are either identical with compounds already known as occurring in Nature, or from their ascertained physiological action have added incalculably to the resources of the physician and surgeon in relieving pain and in curing disease. These include not only drugs for internal administration, but antiseptics, the use of which was only beginning to be recognised at the time of the Exhibition in 1862. (Hofmann's Report, pp. 104–105.)

To these must be added essential oils and other volatile aromatic substances, the application of which to perfumery and flavouring has undergone a stupendous development during the last thirty years.

The innumerable applications of photography have also led to a demand for developing, fixing, and toning materials, as well as for plates and films on a very large scale.

The arts of peace as well as the operations of war have also led to the production of explosives of many new types formerly unknown.

There is also another department of business which requires notice, and that is the demand for pure chemical reagents for analysis and research which has increased to an extent very difficult to calculate, but is manifestly very large. The modern university and technical colleges, nearly the whole of which have come into existence within the last forty years, the large body of Public Analysts appointed under the Sale of Food and Drugs Act, 1875, the establishment in nearly all the public schools and high schools of laboratories for teaching chemistry, as well as the numerous technical laboratories connected with such institutions as the Government Laboratory, the National Physical Laboratory, the Metropolitan Water Board, and many others, afford sufficient evidence that there are several hundreds of chemical laboratories distributed over the United Kingdom in which pure chemicals are required for analytical purposes.

Now leaving to the department of " heavy chemicals " all such things as agricultural and horticultural washes, coarse disinfectants and artificial manures, the question arises, How do we in England stand in regard to the supply of drugs, dyes, photographic chemicals, and

* Gossage's " History of the Soda Manufacture."

perfumes at a time when many of these things are very urgently needed?

It may be safely asserted that the sources of supply of all these materials in the United Kingdom are seriously inadequate. And, further, we may point to the acknowledged fact that many of the dyes, nearly all the synthetic drugs and photographic materials have been systematically imported from Germany.

The Annual Statement of the Board of Trade (p. 108) shows that in 1913 we imported from Germany:—

	£
Alizarin and Anthracene Dyes . .	271,119
Aniline and Naphthalene Dyes. .	1,382,478
Synthetic Indigo	76,681
	£1,730,278

Under the head of "Drugs, unenumerated, including Medicinal Preparations" (p. 107), out of a total of imports from foreign countries and from British Possessions amounting to £1,302,860, more than one-fourth, or to the value of £332,464, was in 1913 received from Germany. From this is to be deducted the inconsiderable amount of dyes and other chemicals from coal-tar, valued at £24,691, exported in 1913 to Germany (p. 300). According to the Final Report on the First Census of Production of the United Kingdom for 1907 (p. 547), this country made 139,000 cwt. of coal-tar dyes, valued at £373,000, of which practically the whole was consumed at home.

As to fine chemicals for analysis and for research, there are no figures available, but it may safely be said that there has been no appreciable production of these things in this country. If such a statement is met by protests from manufacturers who profess to supply these materials it is only necessary to refer to the experience of analysts and directors of research laboratories, which has compelled many of them to resort habitually to German makers for their supplies of trustworthy reagents.

If we are ever to be in a position to supply ourselves and our Dependencies with the dyes, the drugs and the rest of the fine chemicals required in our work, it will only be achieved after a careful review of the circumstances which led to the removal of the industries from this the country in which many of them originated, together with a determination to take to heart the lessons of the past.

A chemical manufacturer, discussing the neglect of fine chemicals in this country, recently made the remark: "What does it matter if we are making money?" I venture to say that that view expresses neither patriotism nor common sense. For the same principles which have served as the basis of the German success in relation to dyes and fine chemicals apply equally to the production of heavy chemicals, and already German chemists have been boasting that, having secured the trade in the former, they are about to attack the latter.

The export trade in sulphuric acid alone is already three times as great from Germany (1912) as from the United Kingdom (1913), as shown by the figures given in the recent Bulletin issued by the Board of Trade. (Commercial Intelligence Branch, October, 1914.)

The recent success of Professor Haber, of Karlsruhe, in the synthetical production of ammonia from hydrogen and atmospheric nitrogen, a process which has been put into operation on an industrial scale by the Badische Company, ought surely to carry something significant to the unprejudiced mind. Neither is it superfluous to point to the extensions taking place in several countries of operations in which the nitrogen of the atmosphere is being fixed in the form of cyanamide, of nitrites and nitrates in which the industrial lead has been taken by Germany, which also supplies a large proportion of the capital, though at present not to the exclusion of the British.

The extent to which the German chemist arrogates to himself the whole field of scientific and industrial chemistry, is illustrated in the report (given in full in *Nature*, 85, p. 558) of a lecture given by Professor Emil Fischer on January 11th, 1911, in the presence of the Emperor, on the occasion of the inauguration of the Kaiser Wilhelm Gesellschaft zur Förderung der Wissenschaften. It is at least unpleasant to hear of a man so eminent as Professor Fischer, and so worthy of respect, treating the subjects of his discourse as though every one of them had originated and been developed in Germany. Perkin is indeed referred to as the discoverer of mauve, but every other foreign name is omitted.

If I now try to recall some of the circumstances which led to the gradual transference of the colour industry from this country to Germany, and the failure to establish here any appreciable production of the synthetic drugs and other chemicals now so urgently needed, it will not be the first time the facts have been stated and the obvious conclusions deduced therefrom.

All the substances referred to belong to the department of organic chemistry, and it might

perhaps be supposed that neglect of this branch of the science by the chemists of this country was the cause of the loss of business. When Hofmann was unfortunately allowed to leave the College of Chemistry to return to his own country, a check was for some time observable in the output of research among us, but it must be remembered that the number of institutons in all countries in which the study of chemistry was pursued was then relatively small. Even in Germany the Chemical Society in Berlin did not come into existence till 1867, and up to that time there had been no laboratory for practical instruction in chemistry in the university of that city.

For the last thirty years, however, the progress of research in this country has gone forward at an increasing rate, though still less rapidly than in Germany. The slow development of chemical teaching and research in this country was attributed by many people to the anti-scientific influences at work in our universities, and especially the older universities. This point of view was exposed very clearly and forcibly by the late Sir William Perkin in presidential addresses delivered to the Chemical Society and the Society of Chemical Industry in 1885. And up to this time it would be indeed difficult to exonerate Oxford and Cambridge from responsibility in the evil example shown by those great seats of learning. But since that day many changes have taken place, and great advances have been made. What is wanted in the British universities is, first of all, that no man shall in future be appointed to a professorship, or indeed to any teaching post in connection with physical or natural science, who does not show his ability to instruct in the higher branches of his subject by the character of the researches which he continues to carry out during his tenure of office; and, secondly, such a change in the curriculum and endowments that there may be not only a supply of instruments and materials but a sufficient body of trained assistants in the form of advanced students to enable the professor to pursue without delay any promising line of investigation.

Notwithstanding the difficulties which stand in the way the scientific chemists of this country are, however, not idle. Evidence of this may be seen in the *Transactions* of the Chemical Society, the volume of which for 1913 contains 238 papers extending over more than 2,300 pages. And when it is remembered that these papers have survived the severe censorship exercised by the Publication Committee of the Society the result must be considered encouraging. It appears, then, that it is not to the scientific part of the chemical world that blame attaches in recent times.

Forty years ago it would be safe to say that there were practically no chemists engaged in the direction of the chemical works of this country, and by chemists I mean fully qualified scientific men. Probably in the palmy days of colour-making it would have been difficult to meet with a British manufacturer who had ever heard of Kekulé's benzene theory, or would have thought it worthy of a moment's notice by a practical man. And yet at the Kekulé jubilee in 1890 a representative of the German coal-tar colour industry declared that the prosperity of Germany in this direction was primarily due to this theoretical conception. Even in much later times the chemical manufacturer in this country has repeatedly had facts laid before him which ought to have attracted his serious attention. One of the most convincing statements was laid before this Society by Professor Meldola on May 13th, 1886, and one would suppose that the figures then given would have been sufficient to create well-founded alarm. For he showed, on the testimony of a considerable number of prominent English dyers, that already about nine-tenths of the colours employed by them were imported from Germany. Again, in a lecture given before the British Association in 1901, on the "Relative Progress of the Coal Tar Industry in England and Germany during the past fifteen years,"* Professor Green showed clearly the steady increase in the imports of dyestuffs from Germany into England, and the steady decline in the production of similar materials in England.

Finally, we have the fact known to all the world that one of the most notable triumphs of German chemical industry is the production of synthetic indigo made from naphthalene on a scale so large as to have almost driven the Indian planter from the field. In this case we have over again a story nearly corresponding to the history of the introduction of artificial alizarin in 1869, an event which was speedily followed by the abandonment of the cultivation of madder in the south of France and elsewhere. And to-day we learn from the Board of Trade statement for 1913 that we imported indigo from Germany to the value of £76,681, while the value of the natural indigo from India has

* Printed in full in the *Journal* of the Society of Dyers and Colorists for December, 1901.

declined from £124,112, in 1909, to £48,208 in 1913. As to the cause of this serious reduction of chemical business authorities are unanimous.

Perkin in the address to the Chemical Society already quoted, attributed the success of the German industries to the employment of high-class chemists. (*Trans. Chem. Soc.* 45 [1884]. p. 219 *et seq.*)

The same view was expressed by Professor Meldola in his paper before this Society in 1886. "The strength of our competitors," he says, "is in their laboratories and not, as here, on the exchanges."

Professor Green stated as his opinion, in the lecture referred to, that the remedy for the present state of affairs can only be found in a better appreciation of the value of science throughout the length and breadth of the land, and that it is not so much the education of our chemists which is at fault as the scientific education of the public as a whole. Nor can much improvement be expected till the public, including manufacturers, can be disabused of the fallacy that a year or two of technical training pumped into an ignorant schoolboy will produce a better works chemist than a university course of scientific study laid upon the foundation of a good general education.

If these are supposed to be merely the prejudiced opinions of British chemists, the sentiments expressed by German manufacturers themselves may be appealed to.

In 1900 a lecture was delivered on the occasion of the opening of the Hofmann House in Berlin by Dr. H. Brunck, since 1884 chief technical Director of the Badische Company, on the "History of the Development of the Manufacture of Indigo." This lecture, in the form of the English version issued by Dr. Brunck, may be fairly regarded as a sermon preached to British manufacturers. Its perusal will convince anyone that the success which has been achieved is the reward of long-sustained investigation in the laboratory of the scientific chemist, and to do justice to this conviction I wish every chemical employer in this country could be induced to read the weighty and eloquent words of the author. He would then perceive that to permanent industrial success there is only one road, and that the way pointed by science.

I will content myself with quoting only a passage or two from Brunck's lecture (pp. 4, 22). "With grateful admiration and reverence do we recall those ever memorable masters, Kekulé and A. W. von Hofmann, whose gifted achievements have laid the foundations of our industry. And when we look back at all the technical achievements we also gratefully recall the fertile discoveries of Graebe and Liebermann, of Peter Griess, and the beautiful researches of Emil and Otto Fischer, of O. N. Witt and the numerous other investigations conducted in our university laboratories, which have acted as incentives for chemical industry, and have furnished the foundation for renewed progress. But first and foremost we are impressed by the mighty influence of the investigations of A. von Baeyer, to whom the coal-tar colour industry is indebted for a great number of important achievements, and who himself has, to-day, unfurled before you the picture of a magnificent scientific creation, from which it was possible for chemical industry to construct and develop one of its grandest achievements.

"But this infant industry was no longer content to be dependent on the gifts which were made to it from various scientific sources. Renowned investigators placed themselves entirely at the disposal of chemical industry; young men in great numbers devoted themselves to it, and grew up with it in enthusiastic and self-directed activity. Such men as Caro, Glaser, Martius, and later on Laubenheimer, Duisberg, Bernthsen, and many others, introduced the spirit of scientific investigation into industrial practice." And, in conclusion, he says: "You have seen that this new industry is not an unexpected gift fallen from the heavens, but that in order to complete the task the intellectual labour and the industry of many men had to be co-ordinated in an organised attempt to attain a definite object for a number of years and throughout a considerable period when success could by no means be regarded as certain. The pre-requisites for practical indigo synthesis were supplied by the results of long years of scientific labour."

In the semi-annual report for April, 1903, issued by Schimmel & Co., the famous manufacturers of essential oils, there are some figures which show the increase of chemical works in Germany and the great increase in the numbers of qualified workmen employed therein, on which the firm makes the following remark:—"The foregoing figures show clearly that the German chemical industry has passed intact through the economic crisis of the last few years. Further, there are no grounds for fearing that it will be outstripped by competition from abroad, so long as the German universities possess such eminent representatives of chemical science."

It is now time to consider what ought to be

done and what it is possible to do in this country to remove reproach from British chemical industry, and to render the Empire independent of supplies from foreign sources.

We need many first-rate chemists, a few engineers, plenty of capital, and some good men of business. A combination of these elements in due proportion is certain of success, and the time, though so unhappy for the world, is favourable for this enterprise.

Inasmuch as the functions of each and the best way of combining them have already been settled in practice on the Continent, it is to be hoped that the ancient precept about being taught by the enemy—*fas est et ab hoste doceri*—will not be forgotten. For there can be no doubt that the principle acted on in all German chemical factories, namely, the employment of the best available scientific skill and the constant appeal to scientific research, has been the secret of their success.

In the British colleges and universities there are many able young chemists, but many more are required. Here education and industry interact on each other. If the demand for scientific assistance were more general, the supply of well-qualified men would soon be greatly increased, and greater attention given by the teachers to the industrial side of the subject. At present other professions in which the prospects are more alluring attract into other lines of work much of the talent of the country. This, however, is not to be interpreted as meaning that there is not now a supply of able young chemists sufficient for immediate needs. The difficulty is to induce chemical manufacturers to treat them reasonably. The pay offered is generally insufficient, and though conditions are somewhat improved of late years, the employer too often expects immediate profitable returns from the engagement of a scientific man. In the Badische works at Ludwigshafen the plan has been to engage university men on the recommendation of their professors for a term of years, at a salary which will enable the new members of the staff to live at least modestly. I am told that in some American works the same system has been adopted. These young men are placed in the research laboratory under the chief chemist controlling the department of manufacture selected, and it is not expected that they will accomplish anything very remunerative at first. But their future depends on their ability and activity, and they act accordingly.

Then there is the position to be accorded to the engineer. He is, of course, indispensable; but the part he should play in the works depends on the nature of the processes involved. So far as relates to buildings and other structures, to supplies of water, fuel, power and electricity, the engineer has the field to himself, but the operations in which materials are to be employed in producing and controlling chemical reactions which lead to the desired product belong to the chemist, and here he ought to be supreme. In some of the old-established operations an engineer with an elementary knowledge of chemistry may carry on for a time, but in these days a chemist with the most extensive and intimate knowledge of physical chemistry is necessary if these processes are to continue to be profitable. As to the production of dyes and other organic synthetical products the operations involved are in many cases so nearly similar to laboratory processes that the chemist requires very little assistance from the engineer.

As to capital, it is necessary to remember that it will have to be provided liberally. A single fact mentioned in Brunck's lecture on indigo, given already fourteen years ago, shows the spirit in which the German manufacturers attacked the problem of the industrial production of this one colouring matter. They had then invested about £900,000 for this purpose.

I will now describe very briefly a modern chemical works. The lantern pictures exhibited show a general view of the works of Schimmel & Co., at Miltitz near Leipzig, first occupied in 1901. The works cover about sixty-two acres. The head office is built over cellars of nearly 22,000 square feet, used as a store for the products of manufacture which, in this case, consist of essential oils and perfumes. The offices are provided with every kind of modern convenience, together with a printing department furnished with electrically-driven machinery. The main building (24,000 square feet) is occupied by stills and other machinery, and in addition there are several laboratories for special manufacturing operations. A feature to which special attention should be drawn is the research laboratory, a separate edifice providing accommodation originally for fifteen chemists, though since enlarged, and containing a library of several thousand volumes, and a museum. The rest of the area occupied by the firm affords space for a number of villas for the resident portion of the staff, and cottages for workpeople. The whole is surrounded by extensive fields in which roses are cultivated.

The works of the Badische Anilin u. Soda

Fabrik, at Ludwigshafen, are arranged on a different plan, because their products are so diversified; but the same principle is recognised, namely, the inseparability of research and manufacture. A number of rectangular buildings, four stories high, are so arranged that the railway lines may traverse the works in two directions at right angles to each other. Each building is devoted to the production of one substance or closely allied group of substances. The top floor is occupied by the laboratory of the chief chemist attached to that department, with several assistants. Below is found an intermediate floor where processes previously tested in the laboratory, or suggested as the result of research, may be tried on a scale sufficiently large to determine their practicability before being transferred to the lower floors where the actual manufacture is conducted. I doubt if anything so complete or so commercially successful exists elsewhere in the world.

How many chemical manufacturers among us can boast that they regard science in a light so serious as to have provided in their works a properly equipped laboratory with a competent staff whose occupation is not confined to the analytical testing of materials or products, but extends to the systematic endeavour to introduce improvements into old methods or the discovery of new ones? A few such enlightened firms do exist, but the figures quoted show how much mischief has already been done.

A variety of other questions have recently been raised in view of the circumstances which have been forced on our notice by the war. There is not time for the discussion of the state of the law as to patents, but a couple of sentences in Schimmel's report for April 1908, show that "great alarm has been caused in the wholesale chemical industry of Germany by the new British Patent Act, which came into force on January 1st, 1908, according to which every patent may be declared void if it is exclusively exercised abroad without sufficient grounds. Many firms are thereby compelled to transfer a part of their production to the United Kingdom, a fact which, in the interests of many thousands of German workmen, is sincerely to be regretted."

With regard to duty-free alcohol, I am informed, on the best authority, that the regulations in this country are now comparable with those of the German Government, and that there is very little ground for complaint. In the vast majority of cases suitably denatured alcohol can be employed without loss or inconvenience.

There has been a good deal of discussion on the subject of trade-marks and proprietary names, much of which I regard as futile. With regard to drugs there should be no great difficulty in instructing the medical profession in those comparatively few cases in which the names are changed.

In conclusion, two remarks only require to be made. The establishment of what will be practically a new industry in this country will require consideration and assistance from the State, if it is to survive the period of fierce competition which will follow the conclusion of the war. Encouragement is already promised to the dye industry, in the form of definite financial aid to be given by Government. But remembering that the colour-maker is dependent on the production of many chemicals, which represent intermediate stages in the processes which lead from the raw materials to the finished product, and that the production of these chemicals is naturally associated with other chemical manufactures, it is to be hoped that the temporary protection will be extended beyond the immediate field of the colour-maker.

The other remark may raise a smile on the part of those business men who are moved only by commercial considerations. There will be a great temptation when the war is over to resume former business relations with the enemy. The German chemical manufacturers have a powerful organisation and many years of experience behind them. Let them keep any markets they can retain outside the British Empire, but every man who cares for his country will surely demand that business at home shall be limited to British goods.

DISCUSSION.

THE CHAIRMAN (Sir William Ramsay, K.C.B., LL.D., Sc.D., F.R.S.), in opening the discussion, said the paper emphasised what we had been told so often during past years, that too little attention had been paid to the scientific side of chemical manufacture in Great Britain. But there were two aspects of the question which had not, he thought, been sufficiently touched on. The present was the time for plain speaking; what was required was a policy; and it was for the scientific and technical chemists of the country to outline the steps which were necessary in order that they might recover their former supremacy. The first aspect was as follows: Trade was regarded in Germany as a war; all means of conquest were looked on as permissible. At the annual meeting of the Society of Chemical Industry in 1903, he had said: "It was the Prussians who first showed how a

modern army should be organised . . . they have at Berlin a council which arranges each particular of each possible campaign; the men are known who will take the command, and from rank to rank the knowledge is spread as to what particular part each officer and each man will have to play in the campaign. The matter is not left to chance . . . An exactly similar policy is being pursued by Germany in the matter of industry. It would be curious if it had not occurred to the persons who are responsible for the military organisation of Prussia that a similar policy is applicable to commerce. It would be remarkable if, having succeeded so well in their military organisation, no attempt had been made to establish a similar commercial organisation; and we shall not go wrong if we assume that there is a council whose proceedings are kept quiet but which takes into consideration the statistics obtainable, and as far as possible legislates, or endeavours to legislate, on the basis of these statistics. Where fiscal duties are found to be wanted, such a council puts them on; where there is an advantage in taking them off, they take them off. Where cheap transit is possible, they let it be given; for the railways are the property of the State. Is it to be expected that any country can fight such a combination as that without adopting, at all events, something of their methods, or without studying their methods, and without combining together, if not to imitate them, at all events to thwart them? . . . There is a military campaign against us, and we must defend ourselves." Many knew that we should be at war with Germany; he personally thought that it would not happen until 1915. It had come earlier, however, and we had been taken unprepared. We now knew the methods of German warfare; and they did not appeal to us, and still less to the unfortunate Belgians. But he hoped we had learned something; that is, that in trade, as in war, the Germans were untrustworthy, unscrupulous, and cruel. He had put the second aspect of the case in a leader in *Nature*, on November 12th. He would quote it. Dealing with the organisation of a German chemical business, he pointed out: "First, the management consists, not in a board of well-meaning elderly gentlemen with a works-manager in their employment, but in a board of specialists, whose business in life is to manage the factory financially, chemically, and as engineers, and who are very highly paid for their services. Second, these gentlemen and a special staff are continuously on the look-out for any scientific discovery or invention which can prove of advantage to their business. Third, a very large staff of men, trained in universities or technical schools, is turned on to the problem of making such a discovery commercial, whether by securing cheap raw material, cheapening the process of manufacture, or creating a public demand for the article to be manufactured. Fourth, a legal staff is maintained, whose business it is to protect by patent all improvements, however apparently trivial, and to describe them so vaguely as to conceal them from their competitors; these gentlemen, in some cases, have also to advise whether piracy is likely to be successful: whether it may not be possible, by infringing a patent, so to saddle an opponent with legal expenses as to break his competition. Fifth, such companies are so powerful that they can influence the central Government to protect all new developments, whether by imposing duties on articles which might possibly compete, by extending bounties to exported products, or by securing advantages in freights to the coast, and in shipping the goods abroad. Sixth, agencies are maintained all over the world whereby the article is introduced to the notice of foreign purchasers; and last, an extensive credit system is encouraged." German competition was thoroughly organised and systematic; their plan had been to attack some material manufactured here, and, by one of the means alluded to, to render its manufacture unprofitable. Having obtained a monopoly, prices were raised. That was a not unusual method of commercial warfare; but it was only in Germany that all the resources of the State were combined to render it easy. How were such tactics to be met? That was, he conceived, the object for the present meeting. First of all, there must be co-operation and trust among our chemical manufacturers. They had to be taught to fight, not each for his own hand, but against a common enemy. Smaller works, which had not funds to maintain an expensive research staff, must combine to obtain efficient laboratories. The products of one works must supplement those of another, and the manufacturers must be organised. Second, competition which was unfavourable, owing to fiscal regulations or patent laws, must be combated by the action of the State, after advice and careful consideration, so that our manufactures and trade might not be unfairly attacked by duties, by export bounties, or by easy freights. He was well aware that he was dangerously near a much-debated political question; but his excuse was that we were now fighting for our life, and as had happened during the present crisis, politics must go to the wall under the pressure of events. All parties in the State must and would work together for the common good. Unless that was our spirit, ruin would inevitably and deservedly overtake us. In conclusion, he would like to remark that such opinions were not entirely his own. That morning he had received from M. Guillaume, Director of the Bureau des Poids et Mesures, at Sèvres, a letter in which the following remarks occurred: "I have seen since the commencement of the war the expression of your opinion of Germany. Like you, I had formerly for Germany a very great admiration, and a real sympathy; but for some years I have recognised from numerous signs that, with rare exceptions, every German possesses the soul of a highwayman and that very few are troubled by scruples. Each one wishes, at the expense of foreign nations, to satisfy gross appetites; and the choice of

means in almost every case is pretty indifferent. I have recognised this tendency in the industry with which I had something to do in past years, but it is equally visible in science, where the principle of annexation flourishes. One thing also struck me in the German tendencies, namely, an inconceivable unconscientiousness. To grab the goods of others appears to them so natural that they do not understand why anyone should wish to resist them. The whole world appears constituted for their own field of exploitation, and anyone who opposes himself to the accomplishment of this destiny is the object, to every German, of surprise. Truly, besides these Germans, and in consequence of an organisation which, all said, we are obliged to admire, life has become very difficult and pretty problematical." It had generally become recognised that the Germans had become a dishonest race, and they must be treated as such.

Professor James J. Dobbie, LL.D., D.Sc., F.R.S., remarked that the author had traced the causes of the unsatisfactory condition in which some branches of chemical industries in this country found themselves at the present time, and he had also indicated where he considered the remedy lay—that there must be more trained chemists, more capital, and a willingness on the part of the chemical manufacturer to employ his capital and to employ trained chemists in his works. He (the speaker) thought it might confidently be said, with regard to the supply of trained chemists, that at present this country was in a better position than ever it had been before. He would like to mention one fact in this connection, namely, that in the smallest of the Scottish universities, owing in the first place to the munificence of a former professor, and more recently owing to the operation of the Carnegie benefaction, a research laboratory had been founded and endowed, which was now well able to hold its own with any laboratory in this country, and with many of the German laboratories. At present there were no less than twelve students there, all of whom were in a position to take part in work to which they had been invited by a committee of the Royal Society, namely, assisting in the production of certain drugs which were necessary for the Army and Navy, and which at present could not be had from the ordinary sources of supply. He thought that was an encouraging circumstance. As to the capital, no one would doubt that that would be forthcoming if it were to be employed for the particular purposes of developing the chemical industries which had hitherto been in the hands of the Germans. But there remained the further point: Were the chemical manufacturers themselves ready to employ the scientific assistance which was needed, and were they ready to remunerate it adequately? Unless they recognised the necessity for the employment of the highest science in the development of their industries very little progress could be made. It was to the education of the masters of the industry that attention had to be devoted; it was those gentlemen who had to be converted. He might mention a fact in illustration of that. He, in his Government laboratory, had recently suffered from the want of chemicals which up to the time of the war there had been no difficulty in obtaining. The laboratory applied in succession to several manufacturers, but not one would undertake the manufacture. It certainly appeared, looking at the process given for the preparation of the particular substance in the text-books, as if it might be a troublesome thing to prepare, but it was essential to the laboratory's work. One of his staff thought he would look into the matter for himself, and in two days he produced a supply of the material adequate for immediate requirements. He could only account for the failure of the manufacturers to supply it on the supposition that they either had not the men in their service or were not willing that the men in their service should devote their time to the study necessary to master the details of the particular manufacture, although if they had manufactured it they would certainly have had a very handsome profit. He thought that showed the necessity of chemical manufacturers employing more largely than they did the scientific services which were now at their disposal in this country. He was glad to see the author had called attention to the fact that, after all, this country had contributed some of the great fundamental principles to chemistry. There was no want of originality in this country; there was no want of initiative; where we had got behind was simply in the power of organisation, or rather the failure to organise.

Mr. A. E. Berry said he had come to the meeting expecting to hear the manufacturers being hotly blamed for the existing state of things, and he admitted that in some instances they deserved that blame; but they had not always received the assistance and help which, in his opinion, should have been afforded to them. A few days ago one of the companies in which he was interested received an inquiry for a certain product that had always been made in Germany. That product required pure free spirit. Knowing from experience that there were very many difficulties and restrictions in procuring pure spirit, the company refused the order. Only the previous day, however, another company of his received the same inquiry, and after considering the matter they said they would make an attempt, and manufacture the product. His company then wrote to the Inland Revenue, saying they had accepted the business and must have duty-free spirit. That day he had received a visit from an officer of that department, who had spent an hour and a half arguing that the product must be made by something else than duty-free spirit. A similar state of affairs existed with regard to hydrosulphate. He claimed that manufacturers in this country had the knowledge and scientific ability to manufacture such a product,

but were debarred from doing so by the Government restrictions with regard to duty-free spirit. One great advantage which German manufacturers had over English manufacturers was with regard to postal facilities. In Germany many highly-priced chemicals and oils were often transmitted by post, and in that respect German manufacturers had an enormous advantage as compared with English manufacturers.

PROFESSOR A. G. GREEN, M.Sc., remarked that the question, as the author stated, was simply one of knowledge. The Germans had considered it was worth their while to pay in order to obtain knowledge; we had not, and until we had changed our methods we should still continue in the same old way. An instance had come under his notice a few days previously which showed the manner in which we were accustomed to proceed in this country. A certain firm in the North of England, of very considerable standing, had their attention directed to a certain substance, and were advised it would be a very profitable thing to take up. Instead of making inquiries as to where they would obtain the best scientific skill and advice as to the manufacture of it, or instead of engaging a chemist, they advertised for a workman who had made the product. They succeeded in getting a workman from a neighbouring manufactory, and the man then immediately said he must have a certain raw material. It was not to be obtained. Then they had to consider the question of manufacturing the raw material. They did not proceed to find out an expert in it, or an engineer to put down a plant, but proceeded to advertise for another workman with a knowledge of its manufacture. He (the speaker) did not know the sequel, but he thought it was pretty clear what it would be. Sir William Tilden considered there were no difficulties with regard to industrial alcohol at the present time. He (the speaker) was of that opinion until a month or two ago, but from inquiries he had made he was no longer of that opinion. The law as it stood would, he thought, if interpreted in a liberal manner, suffice to give all that was required, but as the law was now interpreted it did not. For instance, the price of ether in England was nearly three times as much as it was in Germany. That simply excluded the manufacture in England of a large number of materials in which ether was required. The Excise authorities absolutely refused to allow ether to be made from pure alcohol; it had to be made from industrial alcohol. That put a large extra cost on the manufacture of ether from several points of view. Acetic ether was another product which was debarred from being made from pure alcohol, because the Revenue people considered it would be possible to regenerate alcohol from the acetic ether! Ether was the starting-point of the manufacture of quite a number of fast yellow dyestuffs, which it was impossible to make in this country owing to the fact he had just stated. He did not mean to say that the alcohol question was one of premier importance. The question of the employment of chemists came first. The British manufacturer must employ a larger number of chemists, and he must reward those chemists sufficiently to make it worth their while to do their utmost.

[At this point Sir William Ramsay was compelled to leave the meeting, and the chair was taken by Professor J. M. Thomson, F.R.S.]

MR. A. CHASTON CHAPMAN said it had been truly stated that evening that there were manufacturers in this country who need fear no comparison with any Continental manufacturers. At the same time, the fact could not be hidden that there was a very large body of British manufacturers who imagined that the office was the central and most important part of their works, and that all they had to do was, that if they paid their chemists (if they employed scientific assistance at all) £100 per annum, to ensure that at the end of the year there was £150 in their till. It seemed to him that not only that section of the British manufacturers had to be educated, but also the British public, who in such matters were exceedingly ignorant; and it was through the British public that pressure could be brought to bear on the authorities—where pressure was very badly needed. He considered that this was the only country in the civilised world where chemistry was regarded as being synonymous with pharmacy. When one of the best-known evening papers had an article headed "Developments of Modern Chemistry," and then put under that heading details of new lines in tooth brushes and silver-mounted scent bottles, he considered something very drastic was required to be done. He pointed out that the brewing industry had recognised how much science could do for them. Many of the most important breweries had for many years employed chemists, not merely to examine their materials, but to investigate the conditions of the industry generally, and to see in what way fresh discoveries might conduce to its development.

MR. WALTER F. REID remarked that he was not one of those who grudged the Germans the slightest bit of profit they made out of their own inventions, but what he did say was that when an invention was made in this country and it had to go abroad to be worked, there was something radically wrong in the way the British inventor was treated. He could give dozens of instances where inventors had produced good ideas, but, owing to lack of help and opportunity, had had to let their ideas die or sell them for a mere song. That was not a healthy state of things. He might mention that he invented smokeless powder. In the first place he had taken it to a Government factory, and explained its properties. Some time after an official waited upon him and said that all he claimed for the powder had been proved, but that it could not be introduced into the Army

because, if it was, all the rifles would have to be altered! Was it not sickening to a British inventor when a thing of that kind occurred? There ought to be means available by which anything new of possible benefit might be developed. The Government should assist. British manufacturers were in the position of an untrained mob going against a drilled army, and the fault of that was in the collective effort of what was called the Government. But what was the Government in Great Britain, or the Government in Germany? It was the people, and if we would not combine to help each other it could not be wondered at if the enemy who had combined to beat us gained the victory. The commercial aspect of the matter was, in his opinion, of the greatest importance; he thought it went far beyond a knowledge of chemistry or anything else. The author in his paper had put the business man last. He (the speaker) ventured to suggest that some of the largest and best industries in the country had been developed in the first instance by good men of business. He agreed with Professor Green that chemists must be well paid, but in the first instance the business must be started before there would be anything out of which the chemist could be paid. Professor Green had mentioned the price of ether. Since the war broke out he (the speaker) had started two industries which had hitherto been chiefly carried on in Germany. He tried a third, and ether was one of the materials absolutely necessary. He had come to the conclusion it would be useless to start that industry, because the moment peace arrived the Germans would knock him clean out of the market. He always advised everybody that if they had plant they could utilise for the manufacture of an article let them do so as soon as possible, but if it was a question of spending thousands of pounds on the erection of a plant, unless they had some security that on the conclusion of peace things would not revert to the old unsound state when a foreigner was protected and the Britisher bled, then there was not the slightest chance of their making a profit, and he advised them not to spend the money. The Government were now going to put down public money to help to make certain things. Was that any better? He had yet to learn that a Government manufactory was conducted better than a private one. It all came down to the point that the Government were taking public money to put into a speculation in which a man who owned his own business hesitated to embark his own capital.

Colonel Charles E. Cassal (President of the Institution of Chemical Technologists), said he would attack the question from the point of view of the professional chemist. It was said that plenty of trained scientific chemists were necessary, but it was forgotten that in order to produce the trained scientific chemist a long period of technical education was necessary, which put a very severe tax upon the father of the young chemist. After that, he had to be offered something which was worth his while, and which would attract the right sort of man. What was offered at present to the young budding chemist who was to regenerate the chemical manufactures of this country? The other day he saw an advertisement in the *Chemical News* for a highly trained chemist, who had to be a university honours man, and the salary offered was £65 a year. Not very long ago the editor of a certain journal known as the *Chemical World* published an article in which he said that more trained chemists were wanted, men who would be willing to accept £150 to £200 a year as maximum salaries, in order to direct the operations of the chemical manufactories of this country. If the editor of a publication which was supposed to represent the interests of chemical manufacturers and of chemical technologists, placed the value of the services of a technical chemist at a maximum salary of that amount, and if in the *Chemical News* an advertiser considered he was going to have a highly-trained man for £65 a year, then in his opinion the objects the author had set out in his paper would never be attained. Many manufacturers in this country had followed the objectionable practice of appointing Germans as their chemists in preference to Englishmen, because the former were "cheaper." He hoped that an end would be put to this, and that no German chemists would ever again get appointments in England.

The Author, in reply, drew attention to the fact that he had excluded the question of the brewing industry from his consideration in compiling the paper. As he had said on many previous occasions, the brewing industry had set in the past a most remarkable example to the rest of the manufacturers of this country. He need only mention the names of Graham, O'Sullivan, and Horace Brown, who were scientific chemists and not common testers, engaged by the great breweries in which they worked to investigate their processes and follow them. They did not trouble with the quality of the barley or the quantity of the water and such like details, but investigated all questions connected with the production of the materials which were the subject of their manufacture. Colonel Cassal had referred to a very serious question—namely, the question of remuneration. He quite agreed that the remuneration offered was simply disgraceful. But it had to be remembered that there were hundreds of young German chemists in the same position. The difference between the system adopted in Germany and that in vogue over here was not that the German manufacturer offered a high rate of wage to start with; he offered only enough to enable a man to live modestly until he had shown what he was worth. The man in Germany was carefully selected to begin with; he had had a good training in scientific chemistry, and then he was brought into the works in order to learn his business. That was what the

British manufacturer never could see—that industrial chemistry could never be taught in a college; it could only be learnt in the works themselves. He had noticed two lines in a speech made the other day by Mr. J. G. Jenkins, formerly Premier of South Australia, at a meeting held in London, and he (the speaker) thought there was so much in the remarks that he ventured to read them. Mr. Jenkins said that "much nonsense was talked about the capture of German trade. A certain amount of that trade might be got now, but to keep it the manufacturer must deserve it."

A vote of thanks to the author for his interesting paper was put and carried with acclamation.

LES UNIVERSITÉS FRANÇAISES AUX UNIVERSITÉS DES PAYS NEUTRES.

[In reply to the manifesto recently put forward by certain German professors in defence of German civilisation and humanity, the French universities enumerated have issued the following appeal to the universities of neutral countries. The Royal Society of Arts has been favoured with a copy of this eloquent and convincing statement, and it is printed here in order that the Fellows may have before them the full text of a most interesting and impressive document.]

Les Universités Allemandes viennent de protester contre les accusations dont leur pays est l'objet à l'occasion de la guerre.

Les Universités Françaises se borneront à vous soumettre les questions suivantes:

Qui a voulu cette guerre?

Qui, pendant le trop court répit laissé aux délibérations de l'Europe, s'est ingénié à trouver des formules de conciliation? Qui, au contraire, a refusé toutes celles qu'ont successivement proposées l'Angleterre, la Russie, la France et l'Italie?

Qui, au moment précis où le conflit paraissait s'apaiser, a déchaîné la guerre, comme si l'occasion propice était attendue et guettée?

Qui a violé la neutralité de la Belgique, après l'avoir garantie?

Qui a déclaré à ce propos que neutralité est un mot, que "les traités sont des chiffons de papier," et qu'en temps de guerre "on fait comme on peut?"

Qui tient pour non avenues les conventions internationales par lesquelles les puissances signataires se sont engagées à n'user, dans la conduite de la guerre, d'aucun moyen de force constituant une "barbarie" ou une "perfidie" et à respecter les monuments historiques, les édifices des cultes, des sciences, des arts et de la bienfaisance, sauf dans les cas où l'ennemi, les dénaturant le premier, les emploierait à des fins militaires?

Dans quelles conditions l'Université de Louvain a-t-elle été détruite?

Dans quelles conditions la Cathédrale de Reims a-t-elle été brûlée?

Dans quelles conditions des bombes incendiaires ont-elles été jetées sur Notre-Dame de Paris?

A ces questions, les faits seuls doivent répondre.

Déjà, vous pouvez consulter les documents publiés par les chancelleries, les résultats d'enquêtes faites par des neutres, les témoignages trouvés dans des carnets allemands, les témoignages des ruines de Belgique et des ruines de France.

Ce sont nos preuves.

Contre elles, il ne suffit pas, ainsi que l'ont fait les représentants de la science et de l'art allemands, d'énoncer des dénégations, appuyées seulement d'une "parole d'honneur" impérative.

Il ne suffit pas davantage, comme font les Universités Allemandes, de dire: Vous connaissez notre enseignement; il n'a pu former une nation de barbares.

Nous savons quelle a été la valeur de cet enseignement. Mais, nous savons aussi que, rompant avec les traditions de l'Allemagne de Leibnitz, de Kant et de Gœthe, la pensée allemande vient de se déclarer solidaire, tributaire et sujette du militarisme prussien, et qu'emportée par lui, elle prétend à la domination universelle

De cette prétention, les preuves abondent. Hier encore, un maître de l'Université de Leipzig écrivait: "C'est sur nos épaules que repose le sort futur de la culture en Europe."

Les Universités Françaises, elles, continuent de penser que la civilisation est l'œuvre non pas d'un peuple unique, mais de tous les peuples, que la richesse intellectuelle et morale de l'humanité est créée par la naturelle variété et l'indépendance nécessaire de tous les génies nationaux.

Comme les armées alliées, elles défendent, pour leur part, la liberté du monde.

A NOTE ON THE IMPROVEMENT OF COTTON IN BRITISH INDIA.*

During the rule of the East India Company, when the question of extension of cotton cultivation was first considered, the idea of improving the quality of the crop for the benefit of the people themselves was scarcely considered. A supply of superior cotton capable of competing with the product of America was the definite object of many trials which were undertaken since 1788 onwards.

* Abstract of a paper read by G. A. Gammie, Imperial Cotton Specialist, India, at the Third International Congress of Tropical Agriculture.

The final result of all these trials was that American cotton was introduced into cultivation in the Southern Mahratta Country of the Bombay Presidency, where it still exists. The perennial Bourbon established itself over small areas in Madras, and several species of foreign tree cottons occur in small numbers in gardens and temple enclosures throughout India.

On the organisation of the present Department of Agriculture in India, an attempt was made to find out what were actually the species of cotton in India, their conditions and possibilities of improvement, if such were considered necessary. At the same time many foreign varieties were tested; of the latter, it can be definitely said that all the tree cottons failed on extended trials, and of the exotic annual cottons only a few are promising enough to be persevered with. So far as our knowledge has taken us, it appears that American cottons of high quality can be grown successfully in the irrigated tracts of Sind, Punjab, and parts of United Provinces. In the southern parts of the Madras Presidency, Southern Mahratta Country, and Northern Guzerat there is a strong possibility that a variety of Upland from Cambodia will supply good cotton.

As regards the indigenous varieties, a precise knowledge of these has brought to light the fact that few varieties exist pure in any part of India, and the most valuable work done by the Department so far has been in the separation and extension of the best varieties in the mixtures. For instance, in the Madras Presidency the Karanganni is now grown free from the inferior admixture of the Uppam; in the Bengal areas the white-flowered cottons, on account of their high yield and hardiness, are ousting the other varieties in the mixtures. In other parts of the country where pure varieties have been found a certain amount of improvement has been effected in the staple and ginning percentage; a certain amount of good has also been effected by the substitution of superior for inferior varieties in some districts.

In conclusion, we learn that the purpose of the older experiments was to benefit primarily the English market. The present intention of the work in progress is to benefit the people of the country, and to provide, if possible, a surplus of higher quality for the use of foreign markets.

CONCILIATION COURTS IN FRANCE.

Conciliation Courts dealing with trade disputes between masters and workmen in certain specified industries have long existed in France, where they are known as "Conseils de prud'hommes." These tribunals are established by ministerial authority with the advice of the local chambers of commerce, industrial organisations, and municipal councils, in the important manufacturing and trade centres. Only one tribunal of this character may be established in any city, but it may be divided into independent sections. Workmen and employers are grouped in separate sections.

The "Conseils de prud'hommes" are composed of masters and workmen or employees in equal proportions, and there must be at least two manufacturers or merchants and two workmen or employees in each category, the former being elected by the masters and the latter by the workmen of their group. According to the American Consul-General at Marseilles, the members of the conseils are elected for six years, one half of the tribunal being renewed every three years. In order to take part in these elections the following qualifications are required, namely: (1) Registration on the political voting list; (2) to have attained the age of twenty-five years; (3) to have been engaged for three years, including apprenticeship, in one of the professions or trades mentioned in the decree establishing the court; and (4) one year's residence in the district.

All persons employing for their own account one or more workmen or employees and all members of firms, and managers and assistant managers of industrial and commercial enterprises, and engineers, vote in the category of masters. The electoral franchise is granted in this case to women of French nationality having the necessary qualifications of age, practice of profession or trade, and residence. Electors, including women who have attained the age of thirty years, who are able to read and write, and who have resided in the district for at least three years, and also former electors who have not abandoned their trade or profession for more than five years, and who have been engaged in the practice thereof at least five years within the district, may be chosen as members of these tribunals. Every year, within twenty days after the revision of the political voting list, the mayor of each town in the district, assisted by three electors taken respectively among the masters, workmen, and employees, and selected by the municipal council, writes down on separate lists the name, profession, and domicile of the electors belonging to the various categories. These lists are submitted to the Prefect of the Department for his approval and are afterwards posted in the clerk's office of the tribunal, and in the different town halls of the district. During the fortnight following this publication, application may be made to the local justice of the peace for the correction of the lists. The "prud'hommes," or judges of each section, elect among themselves, by secret ballot and majority vote, a president and vice-president. When the president is chosen among the workmen or employees, the vice-president must be taken among the masters and *vice versâ*.

The president must be in turn a master and a workman. The president and vice-president are elected for one year and may be re-elected. The presidents and vice-presidents of sections meet each year to elect among the former a president of the "Conseil de prud'hommes." One or more secretaries appointed by decree are attached to each tribunal. Each section of the conseil

comprises: (1) a "bureau de conciliation," or conciliation board, and (2) a "bureau de jugement," or judgment board. The conciliation board is composed of one workman or employee and one master. The meetings of this board are held at least once a week, and are not open to the public. The judgment board is composed of an equal number of workmen or employees and masters, including the president and vice-president, who preside in turn. This number includes at least two masters and two employees or workmen.

EMPIRE NOTES.

The Annexation of Cyprus.—In 1878 Cyprus became a British possession, under the terms of a convention between Great Britain and Turkey, by which, on the payment of an annual rent of £92,800, that island was leased by Turkey to Great Britain. Now, by the fortune of war, as we confidently assume that victory will crown the arms of the Allied Forces, that rent will cease to be paid and Cyprus will become an integral part of the British Empire. The island, which has an area of 3,584 square miles and a population of about 290,000, is 900 miles from Malta, and is the third of the important naval bases which Britain possesses in the Mediterranean, the first and most important being, of course, Gibraltar. It may be truly said that from time immemorial it has been the prize of sea power in the Mediterranean. The Phœnicians were among its earliest rulers, and the Greeks succeeded them. As the centuries passed it fell, in succession, under Assyrian, Egyptian, Persian, Macedonian, and Roman rule, and was twice conquered by the Saracens. The English king, Richard I., captured it on his way to the third crusade, and gave it to King Guy of Jerusalem, with whose dynasty it remained till it fell into the hands of the Venetians. In 1570 it was invaded by the Turks, and captured by them after desperate fighting. In the hands of the Turks it continued for three centuries, and under them it steadily declined. According to the convention above referred to, Cyprus is to remain British so long as Kars, Batum, and Poti, which, in 1878, were ceded to Russia by Turkey, remain Russian. The original object in obtaining its cession was to give England a coaling station in the eastern Mediterranean, close to the Suez Canal, from the Mediterranean entrance to which Cyprus is distant only 220 miles, and near the Mediterranean terminus of the Baghdad Railway, which was then projected across southern Asia Minor to India. The occupation of Egypt, however, in 1882, rendered a coaling station unnecessary, since British warships could use the ports of Alexandria and Port Said, while at Cyprus there was no good harbour. Therefore, until 1899 very little was done to develop the interests of the island. But in that year a loan of £314,000 was granted by the British Government, to construct irrigation works, to build railways, and improve the harbours. Sanitation also has been improved and the death-rate greatly reduced. All this has done much to improve the island and to render it a pleasure resort, and to promote its agricultural and viticultural resources. Its chief products are corn, wine, cotton, raisins and fruits.

An Imperial Highway.—One of the arguments in favour of the construction of the Canadian Pacific Railway, years ago, was that it would prove an important Imperial highway between the United Kingdom and India, as troops might be conveyed by it, in case of need, from England to India. But although that particular necessity has happily not arisen, the C.P.R. has been able to render great service to the Dominion of Canada and to the Empire in various ways—first, by the rapid transport of troops across the continent from British Columbia and the western prairies to Quebec, Halifax and St. John; secondly, by placing at the service of the naval authorities a number of their best ships, now transformed into auxiliary cruisers, which are to-day traversing the seas to defend our trade routes, and to look for the ships of the enemy; and, thirdly, by making large contributions from the company itself and their staff to the war relief funds, and by the personal services of many of their men. So far as the transport work is concerned, it is gratifying to know that the arrangements made for handling the troops and for looking after their general comfort were all carried out without interfering with the company's current time-tables. The public were, therefore, in no way inconvenienced, while, at the same time, a service was rendered to the Empire of the greatest value.

The Commonwealth Wheat Position and Prospects.—According to the *Australian Insurance and Banking Record*, the stocks of wheat and flour at present in the Commonwealth leave only a moderate surplus available for export before next harvest, after providing for Australian consumption. The last harvest, as shown by official returns, amounted to the record total of 103,589,369 bushels. After providing for consumption of food and seed, this total would leave an exportable surplus, for the whole season, of between 65 and 70 million bushels. Allowance, however, would have to be made for a certain quantity of stock to be carried over at the end of the season, and for the possibility of over-estimates. Since the middle of last December the exports from the Commonwealth, including flour reduced to the equivalent of wheat, have amounted to nearly 60,000,000 bushels, so that most of the surplus has been exported. As regards prospects for the present season, it is stated that the New South Wales area sown for grain is officially estimated at 3,556,386 acres, or an increase of 350,989 acres as compared with the season 1913-14, while the Victorian area from grain is officially estimated at 2,679,500 acres, or an increase of 113,639 acres, making a total increase of 464,628 acres in the

two States, which, last season, represented about 62 per cent. of the total area under wheat in the Commonwealth. Unfortunately, in a considerable area of Victoria and New South Wales, and of other States also, the rainfall, until recently, has not been more than sufficient for current progress. So long, therefore, as the course of the weather continues problematic, the farmers will be unwilling to sell the remainder of their wheat held over since last season, and for this reason, if for no other, a firm market would be experienced, apart from the influence of the war. To meet the exigencies of the war, efforts are being made to continue, as far as possible, the exportation of wheat and other foodstuffs to the United Kingdom and to our Allies. This applies also to the exportation of hides and skins, which, by a recent proclamation, is prohibited, without the consent of the Minister of Customs, with a view to preventing the articles from reaching the enemy. The extensive purchases of Australian sheepskins by American merchants has caused comment, in view of previous limited shipments to the United States. It is believed that the ultimate destination of a large quantity of these purchases would be Germany. This will henceforth be controlled by the regulation of exports of hides and skins now to be enforced. Similar provisions are being made in New Zealand in regard to the export of wool, which had previously been adopted in reference to that article in Australia. By these timely and practical measures, Australasia is seeking to help the Mother Country by foiling the attempts of the enemy to obtain the raw materials so urgently required by Germany and Austria.

The Question of Responsible Government in Rhodesia.—By Clause 33 of the British South Africa Company's Charter of October 29th, 1889, the power is reserved to the Crown, at the end of twenty-five years from the date of the Charter, and at the end of every successive period of ten years, to add to or repeal any of the provisions of the Charter relating to administrative and public matters. Failing the exercise of this power by the Crown at the end of these prescribed periods, the Charter is automatically extended for another ten years. Last year, when the twenty-five years stated in the document of 1889 had expired, an election was held, at which a vote was taken on the question of responsible government. The result of that election, it will be remembered, was that the advocates of responsible government for Southern Rhodesia were decisively defeated, and the rule and governance of the Company were fully confirmed. It was therefore concluded that there would be no interference with the administrative position of the Company for another ten years. The directors of the Company, however, have recently informed the Colonial Secretary that they would not regard the non-exercise by His Majesty of his right of reviewing the provisions of the Charter during the next decennial period as any bar to the establishment of responsible government should the time appear to be ripe for such a step; and that if, during these ten years the inhabitants of Southern Rhodesia should find that they were financially and in other respects strong enough to assume, with the concurrence of His Majesty's Government, the burden of administration, and should express, through the Legislative Council, their desire to assume that burden, they, the directors, would be most willing to give effect to that desire. In view of this liberal and broad-minded attitude on the part of the Company, the Government have decided not to exercise their powers, but in due course will issue a Supplementary Charter giving effect to the arrangement to which the Company have agreed, in respect of the possible future establishment of responsible government.

CORRESPONDENCE.

MAP-MAKING AND TAPESTRIES.

In the course of his extremely interesting and enlightening remarks upon map-making at the opening meeting of the session, our Chairman of Council, Sir Thomas Holdich, referred to the lead given to Europe in the sixteenth century by Dutch map-makers. In this connection I should like to draw attention to English sixteenth and seventeenth century map tapestries, lent to the Victoria and Albert Museum and now exhibited there. Some are complete and large wall hangings of pictorially conventionalized maps of Warwickshire, Oxfordshire and adjacent counties; some are mere fragments. Long accounts of their origin, of presumptions as to the engraved maps from which the tapestry weavers' cartoons may have been made, of circumstances of their preservation, etc., are placed near them, but there is, as well as I can remember, no suggestion of their relationship to similar styles of tapestries made in Holland at corresponding, if not at earlier, times. For instance, I saw in April this year a well-preserved specimen of kindred topographical character hanging in the Municipal Museum of Leyden. Its subject is the relief of Leyden in 1574, and the tapestry was made in Delft from cartoons by Liefring and Swanenburg. Tapestry manufacture at Delft was carried on under the direction of Francis Spiring, or Spierinx, and one class of the designs which he adopted was of a character at least allied to that of the English map tapestries—that is to say, it was pictorially diagrammatic, so to speak. Similar pictorially diagrammatic tapestries woven late in the sixteenth century at Middleburg hang in the Council Chamber in the extensive buildings of the old Abbey there. These tapestries represent the naval battles between the Dutch Maritime Provinces and the Spaniards, and are also of a distinctly topographical design, similar to one or two specimens now at Hampton Court Palace, of engagements between the English and Spanish

Fleets in 1588. These Middleburg and Hampton Court tapestries were woven from designs by H. Cornelius Vroom of Harlem. Was he a map-maker as well?

Sir Thomas Holdich told us how Jerusalem was indicated by old map-makers as being the centre of the world. The pilgrimage of Otto Heinrich, Count Palatine and Duke of Bavaria, to the Holy Sepulchre at Jerusalem, in 1521, is the subject of a mixed topographical and special, or story-telling design, woven in a large tapestry hanging now in the Industrial Art Museum of Munich. In this is represented a detailed view—more Dutch than Oriental—of Jerusalem set in the midst of hills.

These, then, are a few instances of topographical designs and their production in the sixteenth and seventeenth centuries as tapestries. I venture to suggest that the authorities of the Victoria and Albert Museum might well develop their inquiries in this direction in order to encourage the study and comparison of kindred classes or types of design for tapestry weaving. Their minute investigations to prove the English or other national origins of tapestries are perhaps delightful as antiquarian and ethnological pursuits, but these are not very helpful to the student of phases of decorative design in its relation to manufactures, and this is surely the prime educational purpose of the Victoria and Albert Museum.

Alan S. Cole.

November 20th, 1914.

OBITUARY.

Alfred Sang.—Mr. Alfred Sang was born in Paris in 1876. His parents were English, and he was educated, first in France, later at Ratcliffe College, England, and subsequently at the Conservatoire National des Arts et Métiers in Paris. He was possessed of considerable mathematical and mechanical ability, and before going to the United States, in 1900, he invented a calculating machine. In Pittsburg he was identified with the Garland Companies, and specialised on the corrosion of metals and metallic coatings for the prevention of corrosion. He wrote a book on this subject, and was a well-known contributor to many scientific publications. Returning to Paris in 1909, he founded the company of Sang and Rafinesque, metallurgical engineers, and later on he established the firm of Sang and Russell in London. On the outbreak of the war he at once volunteered for the Intelligence Corps. He was especially fitted for this service as he spoke French and English equally well and had also a thorough knowledge of German. The roads of Northern France were perfectly familiar to him, as he was an ardent cyclist. Unfortunately he was wounded in the head early in September, and died in the British Military Hospital at Rouen on October 2nd. Mr. Sand was elected a member of the Royal Society of Arts in 1911.

NOTES ON BOOKS.

The Guitar and Mandolin: Biographies of celebrated Players and Composers for these Instruments. By Philip J. Bone. London: Schott & Co. 1914.

This book, as the author states in his preface, is the result of his coming up to the Society's Examinations in Practical Music in 1897, when he obtained the Society's Medal. Dr. John Farmer, the examiner, was so struck with his playing that, with his usual kindliness, he kept up a correspondence with Mr. Bone, in which he strongly urged him to devote himself to the study of music and musical history.

The book itself is really a biographical dictionary of players on the two instruments mentioned, and of composers of music for them. It shows a very great amount of research, and may be taken to include a complete account of all known guitar and mandolin players, while it also includes a large number of well-known composers who wrote music intended for the mandolin or guitar, though they certainly cannot be said to have devoted themselves in any sense to the special production of such music. For instance, Beethoven, Berlioz, Gounod, Mozart, and very many other well-known names are all included. But to judge from the pains evidently taken by the author in the production of the book, it may fairly be assumed that as regards players of the two instruments mentioned, it may be accepted as exhaustive.

The illustrations, which are all reproductions of portraits, are not very satisfactory, though they certainly add to the interest of the book.

Celtic Scribe Work. By J. F. Maxwell. Dublin and Belfast: The Educational Company of Ireland. 9*d*.

This is a copy-book in which the author has collected some specimens of Celtic script. They are, for the most part, examples in outline taken from "The Book of Kells," "The Book of Durrow," and "The Book of Lindisfarne," though a few original pieces based on designs from these manuscripts have also been added. The extraordinary beauty of the work of the Celtic scribes is, of course, familiar to most people, and although much of it is due to the beautiful colouring of which they were masters, still it is wonderful to see how much remains when only the bare outline is left. One of the most striking pages is that containing examples of interlaced repeating borders, where are shown the different effects produced in precisely the same outlines by varieties of shading.

The art of illumination is a very beautiful one, and no country has produced finer work of this kind than Ireland. It is to be hoped that the production of this copy-book may achieve the end which the author had in view—"enable the student to grasp the most salient characteristics of Celtic art, and so lead him on to the study of the more ambitious works on what is generally admitted to be the most beautiful script in the world."

GENERAL NOTES.

THE PANAMA-PACIFIC EXPOSITION.—The United States Government has placed its steamship "Jason" (15,000 tons) at the disposal of all British exhibitors who desire to take part in the Panama-Pacific Exposition, to be held at San Francisco. The "Jason" has just reached this country with Christmas presents for the children who have suffered bereavement through the war, and is expected to sail on her return journey from Plymouth or Falmouth about January 1st. She will go through the Panama Canal and take British art and industry exhibits direct to the exhibition wharf in San Francisco, without any charge for freight. A notable advantage of this arrangement is that it assures the safety of all exhibits from a British port to the Exposition through waters that have recently been visited by German cruisers. British firms desirous of availing themselves of the "Jason" are asked to communicate, as soon as possible, with the Exposition's London offices, Trafalgar Buildings.

ALUMINIUM.—Some interesting figures representing the remarkably rapid development in the production of aluminium were given by Mr. H. N. Munro, in a paper recently read before the Junior Institution of Engineers. The price per ton in 1889 was £3,256, in 1891 it was £812, and it has decreased until now it is in the neighbourhood of £80. As aluminium is one of the lightest of metals, weighing 160·167 lbs. per cubic foot, it is greatly in demand where light weight is of importance. It is very malleable and ductile, does not tarnish or rust, and is not affected by the action of water. The metal is produced electrically from alumina, an oxide of aluminium, which is obtained from bauxite, a clayey ore containing about 55 to 56 per cent. of alumina. For electrical purposes aluminium is fast becoming common. Overhead transmission lines constructed in aluminium show a great saving over equivalent copper lines, a saving of as much as 10 to 25 per cent. being effected, according to the size and nature of the system erected. Its freedom from corrosion renders it an admirable metal for use on lines in the vicinity of chemical works, etc., and in seaside places, where the air is permeated with salt, etc. Among the aluminium lines erected in this country are:—Three-phase H.T. lines from Aldershot to Enshott, and from Tidworth to Bulford, both for the War Office, lines for Weardale Steel, Iron and Coal Company; Ebbw Vale Steel, Iron and Coal Company, North Wales Power and Traction Company, Fife Coal Company. For insulated cables, aluminium is extensively used, particularly on the Continent, where some hundreds of miles of aluminium mains, principally paper head covered, are laid. For very small cables and heavily-armoured cables, aluminium may now show up to the same advantage as for ordinary sized cables, but even in those two classes aluminium cables can effect a saving of 5 per cent. and upwards, according to the design of the cable. The joining of aluminium cable in the earlier days was a difficult problem, and is still regarded as a great drawback to the use of aluminium. Provided, however, that the joints are carefully made and all moisture excluded, aluminium can be easily and effectively jointed. Many kinds of mechanical clamps are available which are very effective. The uses of aluminium in the manufacture of magnet coils, for use as bus bars and battery connections was described. For use in the construction of railway and motor vehicles for domestic, military, and general purposes, aluminium finds an extensive field.

THE DAIRY INDUSTRY IN EASTERN SIBERIA.—There is a shortage of meat and milk cattle in the Maritime Province. Most of the meat is received from neighbouring countries, while the butter supply comes from western Siberia. These conditions have awakened considerable interest in the development of breeding local cattle to furnish necessary supplies, and steps are being taken by the Government to give strong support to this industry, which is a growing one. In the opinion of scientists, a further plan of teaching the peasantry methods of keeping and feeding cattle, and caring for the young animals, will have a good influence on its development. Nearly all dairy products are obtained during the four summer months. As the population knows little about local butter, and as the dealer is bound by contracts with western Siberian firms, they have not taken sufficient interest in it, for which reason the marketing of local butter has not been easy. Until the population becomes acquainted with local products, the agronomical organisation sees the necessity of controlling the sale of these meat products. The estimates of this organisation for the year 1914 contain sums for the construction of a Government cold-storage plant at Vladivostok, and a similar one will soon be constructed in Habarofsk.

PRICES OF PROVISIONS ON THE FRENCH RIVIERA DURING WAR TIME.—The *Commission d'Alimentation*, of the Department of the Alpes Maritimes, with a view of regulating the cost of provisions in this Department, have fixed the following prices as the limit to be charged: wheat, 28 francs per quintal (11*s*. 8*d*. per English cwt.); flour, 39·50 francs per quintal (16*s*. 0½*d*. per cwt.); and rice, 37 francs per quintal (15*s*. per cwt.). Owing to the intervention of the municipality the price of bread at Nice has not risen, and remains as it was before the war at 45 centimes per kilogram (2*d*. per lb.). Sugar, the retail price of which ranged from 60 to 70 centimes per kilogram (2¾*d*. to 3¼*d*. per lb.), has lately risen to as much as 1·30 francs per kilogram (6*d*. per lb.). A good light table red wine (*vin ordinaire*) of this year's vintage is now retailed as low as 35 centimes per litre (2*d*. per pint) as compared with 50 centimes per litre last year.

Vegetables and fruit are plentiful and cheap, with the exception of potatoes, which have risen considerably in price. Eggs and butter are slightly dearer than last year.

IRON IN ANCIENT INDIA.—A great deal of scattered but highly interesting information regarding the manufacture of iron in India in early times has been brought together in a pamphlet by Mr. Panchaman Neogi, Professor of Chemistry at the Rajshahi College. He finds evidence of its manufacture in India as far back at least as 2000 B.C., and from a passage in the "Black Yajurveda" it seems that some form of iron cannon had been used in the Vedic age between 2000 and 1000 B.C. Later, between 500 and 200 B.C., iron appears to have been largely used, more especially for warlike weapons. Probably, however, the most remarkable instance of its employment appears in a medical work describing nearly one hundred surgical instruments used for most delicate operations, a piece of evidence which seems to show that the manufacture of steel must have been well understood. From certain burial sites in the district of Tinnevelly iron swords and daggers have been unearthed, but the exact age of these cannot be fixed, though they are believed to have come down from prehistoric times, and specimens of third-century iron have been recovered from Buddha Gaya. The iron pillar near the Kutub Minar, Delhi, is of course well known, while the relics at Konarak and Puri are also celebrated. The date of the former is ascribed to A.D. 640, and that of the rectangular iron beams at Puri to A.D. 1174. The sixteenth century saw the first manufacture of cannons in India, when some of a remarkable size were turned out. The reader will find it difficult, after perusal of Mr. Neogi's pamphlet, to understand how it has come to pass that metallurgical experience and knowledge should have disappeared to such an extent from the country as it now appears to have done.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

DECEMBER 2.—WILLIAM REGINALD ORMANDY, D.Sc., F.C.S., "Britain and Germany in Relation to the Chemical Trade." The Right Hon. LORD MOULTON, LL.D., F.R.S., will preside.

DECEMBER 9.—WILLIAM A. YOUNG, "Domestic Metal Work of the Eighteenth Century." PROFESSOR WILLIAM GOWLAND, F.R.S., will preside.

DECEMBER 16.—SIR WILLIAM DE WIVESLIE ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "Testing Pigments for Permanence of Colour."

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock :—

DECEMBER 17.—DR. F. MOLLWO PERKIN, F.I.C., F.C.S., "The Indian Indigo Industry." SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., will preside.

Papers to be read after Christmas :—

F. VINCENT BROOKS, "British Lithography in 1915."

Hon. JOHN COLLIER, R.O.I., "Portrait Painting."

OCTAVIUS CHARLES BEALE, Chairman of the Australian Manufacturers' Association, "Imperial Industrial Development after the War."

THOMAS WORTHINGTON, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. THORNE BAKER, "The Industrial Uses of Radium."

FRANK BAINES, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

G. W. HULME, "Patent Law."

W. T. THORNTON, "The Industrial Uses of Coal Gas."

D. Y. CAMERON, A.R.A., R.E., "Etching."

ROGER FRY, "Post Impressionism in Design."

C. H. SHERRILL, "Ancient Stained Glass."

WILLIAM POEL, "Shakespeare's Profession."

ARTHUR WILCOCK, "Designing for Textiles."

J. A. HUNTER, "The Textile Industries of Great Britain and of Germany."

EDWARD R. DAVSON, "Colonial Sugar Development."

HENRY JOHN ELWES, F.R.S., "Nepal."

CAPTAIN SIR GEORGE DUFF DUNBAR, Bart., I.A., "Tribes of the Brahmaputra Valley."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

January 21, February 18, March 18, April 15, May 13.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

February 2, March, 2, 30, May 4.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

R. A. PEDDIE, Librarian, St. Bride Foundation Typographical Library, "The History and Practice of the Art of Printing." Four Lectures.

LECTURE II.—NOVEMBER 30.—*The 19th Century.* In 1801 no machine production—Stanhope press—Type faces 1801-40—Revival of old style printing

and Caslon type—Machine-made paper—Development of the printing machine—Invention of photography—Attempts at colour printing.

LECTURE III.—DECEMBER 7.—*The 19th and 20th Centuries continued.* Woodcuts of the Sixties —Invention of the half-tone—Revival of hand-press work for artistic production—Effect of revival on commercial work—Types and Typefounders—Recent inventions in illustration.

LECTURE IV.—DECEMBER 14.—*The later history of colour printing*—Rise of chromo-lithography—Chromo-xylography—The three-colour process—Collotype—Photogravure and its combinations—The offset process.

DR. F. MOLLWO PERKIN, F.I.C., F.C.S., "Oils, their Production and Manufacture." Three Lectures.

January 18, 25, February 1.

M. H. BAILLIE SCOTT, "House Building Past and Present." Three Lectures.

March 15, 22, 29.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evenings, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

February 15, 22, March 1.

JUVENILE LECTURES.

Wednesday afternoons, at 5 o'clock:—

H. PLUNKET GREENE. Two lectures, with vocal illustrations.

January 6, 13.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. R. A. Peddie, "The History and Practice of the Art of Printing." (Lecture II.)

Brewing, Institute of (London Section), The Imperial Hotel, Russell-square, W.C., 8 p.m. 1. Annual General Meeting. 2. Mr. H. E. Field, "What Economies, if any, are possible in the Brewery to-day?"

Actuaries, Institute of, Staples Inn Hall, Holborn, W.C., 5 p.m. Inaugural Address by the President, Mr. Ernest Woods.

TUESDAY, DECEMBER 1...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. L. Gaster, "Illuminating Engineering in War Time. Some Lessons to be learned from the present lighting of London."

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. 1. Mr. J. B. Ball, "Tests of Reinforced-Concrete Structures on the Great Central Railway." 2. Mr. S. H. Ellis, "Corrosion of Steel Wharves at Kowloon." 3. Mr. J. Hammersley-Heenan, "Concreting in Freezing Weather and the Effect of Frost upon Concrete."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. G. B. Clifton, "The Bromoil Process."

Horticultural Society, Vincent-square, Westminster, S.W., 3 p.m.

Roentgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m.

Medicine, Royal Society of, 1, Wimpole-street, W., 5 p.m. Dr. D. B. King, "Some Recent Experiences of Germany in War Time (during Detention in Germany) and their Lessons."

WEDNESDAY, DECEMBER 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. W. R. Ormandy, "Britain and Germany in Relation to the Chemical Trades."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Dr. S. J. Lewis, "Application of Spectrography to Analysis." 2. Messrs. E. R. Bolton and E. M. Jesson, "Note on some Oleaginous Seeds." 3. Mr. G. N. Huntly, "Corrections in Bomb Calorimetry." 4. Mr. G. D. Elsdon, "Note on the determination of Sulphates in Flour."

Entomological Society, 11, Chandos-street, W., 8 p.m.

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Dr. Annie Abram, "Misericords in Bruges Cathedral."

Civil Engineers of Ireland, Institution of, 35, Dawson-street, Dublin, 8 p.m.

Medicine, Royal Society of, 1, Wimpole-street, W. Section of Ophthalmology, 8 p.m. Mr. H. B. Grimsdale, "The Necessity for an Exact Definition of Blindness."

THURSDAY, DECEMBER 3...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 8 p.m. 1. Mr. R. C. McLean, "An Ecological Journey in South America." (Illustrated by lantern-slides.) 2. Messrs. C. West and Hisayosin Takeda, "On *Isoetes japonica*, A. Br."

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 7.30 p.m. Margaret Conner, "Self-Expression through Language with Older Children."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Mr. H. V. A. Briscoe, "A Redetermination of the Atomic Weight of Tin." 2. Messrs. O. D. Brady and F. P. Dunn, "The isomerism of the oximes. Part VI. p-Dimethylaminobenzaldoxime." 3. Messrs. F. Challenger and C. F. Allpress, "Organo derivatives of bismuth. Part II.—The stability of derivatives of quinquevalent bismuth."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Rev. J. Stephenson, "The Bible; its Manuscripts and Translations."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. H. Kempton Dyson, "Shear and Problems arising therefrom."

Art Workers' Guild (Junior), 6, Queen-square, W.C., 8 p.m. Mr. G. P. Bankart, "The Decorative Uses of Plaster."

FRIDAY, DECEMBER 4...Chadwick Public Lecture, at the London School of Economics, Clare Market, W.C., 8.15 p.m. Sir R. Ross, "Government and Military Sanitation in the Tropics." (Lecture I.)

Geologists' Association, University College, W.C., 8 p.m.

Engineers, Junior Institution of, 39, Victoria-street, S.W., 8 p.m. Mr. S. E. Hutson, "A Reversible Turbine."

Journal of the Royal Society of Arts.

No. 3,237. VOL. LXIII.

FRIDAY, DECEMBER 4, 1914.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 7th, at 8 p.m. (Cantor Lecture.) R. A. PEDDIE, Librarian, St. Bride Foundation Typographical Library, "The History and Practice of the Art of Printing." (Lecture III.)

WEDNESDAY, DECEMBER 9th, at 8 p.m. (Ordinary Meeting.) WILLIAM A. YOUNG, "Domestic Metal Work of the Eighteenth Century." PROFESSOR WILLIAM GOWLAND, F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, November 30th, MR. R. A. PEDDIE delivered the second lecture of his course on "The History and Practice of the Art of Printing."

The lectures will be published in the *Journal* during the Christmas recess.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 6th and 13th, 1915, at 5 p.m., by MR. H. PLUNKET GREENE, on "How to Sing a Song."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, December 2nd, 1914; the RIGHT HON. LORD MOULTON, P.C., LL.D., F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Smith, Rev. Professor Samuel George, D.D., LL.D., Ph.D., St. Paul, Minnesota, U.S.A.

Tyrer, Thomas, F.I.C., F.C.S., 14, Sandwell Mansions, West End-lane, N.W.

The following candidates were balloted for and duly elected Fellows of the Society:—

Agramonte, Albert Arthur, Assoc.M.Am.Soc.C.E., Direccion de Desagües, Dolores, Argentina, South America.

Baijal, Kewal Ram, Chandni Chowk, Delhi, India.

Baldwin, John Brake, 6, Phillimore-terrace, Kensington, W.

Barth, Jakob Christian, British Vice-Consul, Sundsvall, Sweden.

Bell, William, C.I.E., M.A., 16, Summerside-place, Trinity, Edinburgh.

Bhandarkar, Hon. Chief Justice Vasudeo Gopal, Baroda, Baroda State, India.

Bilstein, Emma L., M.D., The Mount Royal, Baltimore, Maryland, U.S.A.

Bullough, Charles John Robert, The Willows, Warwick Road, Bounds Green, Middlesex.

Burnett, Eric Vaughan, M.Inst.M.M., Villas Harrington No. 7, Camino Cintura, Playa Ancha, Valparaiso, Chili, South America.

Carr, George, 22, Clapton Common, N.E.

Clarkson, Thomas, Talara, Payta, Peru, South America.

de Quesnel, George Marinus, c/o Messrs. Edwards & Sons, 57, Moorgate-street, E.C.

Duggall, Dewan Hari Gopal, Wazirabad, Gujranwala District, Punjab, India.

Dunlap, Professor Frederick, University of Missouri, Columbia, Missouri, U.S.A.

Gould, Charles Newton, Ph.D., 408, Terminal Building, Oklahoma City, U.S.A.

Gray, Mrs. Horace, c/o Messrs. Baring & Co., 8, Bishopsgate, E.C.

Gunn, James, 9, Gladstone-street, Hartlepool.

Gupta, Karunakumar Dutta, M.A., B.E., 70, Lansdowne-road, Calcutta, India.

Harrison, Cecil Reeves, B.Sc., Woodcote, Chislehurst, Kent.

Hill, Lewis George, 5, Oxford-road, Acocks Green, Warwickshire.

Langton, Miss Eveline Charlotte, Underhills, Beech-road, Reigate, Surrey.

Lewis, Rev. Edward Pilcher, D.D., St. George's Parsonage, 4 Rua da Estrella, Lisbon, Portugal.

Mackillop, John Archibald, Cumbrae, Mosman, Sydney, New South Wales, Australia.

Mews, John, LL.M., 90, Westbourne-terrace, W.

Munavery Sahib, Dr. P. M. I., Chalai P.O., Trivandrum, South India.

Narain, Parshottam, Farrukhabad, United Provinces, India.

Nash, Alfred William, Apsheronskaya, Kuban Province, South Russia.

Recke, George Philip, St. Thomas, Danish West Indies.

Rodger, Norman, 131, Cromwell-road, S.W.

Rogers-Moore, Mrs. Alice, 132, Winsor-avenue, Watertown, Massachusetts, U S.A.

Royce, William Stapleton, J.P., The Hall, Pinchbeck, Spalding

Sen, Hon. Rai Bahadur Nisi Kanta, B.L., Purnea, India.

Sircar, D. K., Sukchar Dyeing Factory, Sukchar P.O., 24, Purgannas, Bengal, India.

Skeet, George William, The Blue Coat School, Frome, Somerset.

Smith, Henry Lee, M.A., M.D., 2701, Calvert-street, Baltimore, Maryland, U.S.A.

Taylor, Guy Arthur, B.A., Solwezi, Northern Rhodesia.

Thornton, Horace Moore, The Richmond Gas Stove & Meter Co., Ltd , 132, Queen Victoria-street, E.C.

Westgate, John Minton, United States Department of Agriculture, Washington, D.C., U.S.A.

The Chairman (the Right Hon. Lord Moulton, P.C., LL.D., F.R.S.) said, that owing to public business he would, to his regret, be compelled to leave the meeting before the paper was read. He was glad, however, of the opportunity of being able to impress upon them that which the last few weeks had impressed upon him more deeply than he could express. He had had allotted to him for several weeks past the business of investigating into the question of the supplies of articles of which we were now deprived by reason of the war with Germany—that was to say, articles which in peace time were imported from that country. It would occur to all of his hearers that, first and foremost of those had been the problem of the great chemical trades, especially the great industry in synthetic dyes, and he had had an opportunity of marking in detail those things in which England had allowed herself to be supplied in chemicals from Germany. He could assure the audience that he had noted the fact with great sadness, and, he was bound to say, it was a great national humiliation. The fact was that chemistry opened up, especially some fifty years ago, a domain of industrial wealth which he could only compare to the domain which was opened up when steam power was first invented; and to his great sorrow he could come to no conclusion but one, and that was, that either from being too well off, or from sluggishness of intellect, or from the fact that the capital of the country had passed into the hands of people who were unwilling either to learn or to think, England had abstained almost entirely from attempting to reap the rich harvest that was opened to the industrial world by the advances in organic chemistry. The fact was too well marked for us to pass it by as being a mere incident in national life. Of course, no one thought that every nation could do everything; and that nations should, to a certain extent, specialise, should take advantage of their natural position, and the deposits that they found in their land, their climate, and things of that kind, was not only normal but desirable. But thought depended on no climate. Thought was open to us all; and the fact that England neglected the chemical industries could not be explained away by any suggestion that it was either incapable or for any natural reason unfitted for their pursuit. One had to look deeper than that. One had to find some fault either in the national character or in the national behaviour which would account for it; and he did not believe that England could, after the war, survive as a great industrial nation if she did not correct that fault, if she did not make an effort to take her place—and that an uppermost place—in the world of industry in chemical matters as well as in all others. If the conclusion was come to that it had been by a national fault that we had missed it in the past, and that we were not going to live a disgraced life in future, it meant that that fault must be corrected, and found out for the purpose of avoiding it, and there, he thought, a lesson might be taken from our enemies. To his mind by far the most glorious moment in the history of Prussia was not the moments of her military successes—it was the moment of her deepest disaster. Those who knew Prussian history would remember that after the nation had been prostrated by Napoleon in the Battle of Jena the national independence was utterly taken away. The restrictions the conqueror put upon them were humiliating in

every way. At that time there arose a set of men, of whom he chose to name, first, Fichte, who told the Prussian people in the clearest language that their disaster was due to their national faults, and pointed out the way that they must correct those, and in the most unsparing language he told them that it was only by self-discipline, only by taking to heart their disaster, seeing in it the natural consequence of their national faults, that they could possibly get the resolution or the strength to replace their nation in the position which it ought to occupy. The whole nation listened. It was at that time that the Germans took to physical development and voluntary drilling. They prepared themselves in every possible way for that coming fight which they hoped they would have with their oppressors, and which they had in the course of very few years, but they did it under the exhortations of these men, because they did not attempt to hide from themselves that it was the nation that was to blame for its misfortunes. He was not talking of as grave matters as those of which Fichte spoke, but our position in the industrial world, to maintain for England the glory in peace which it had always esteemed even more than its glory in war, was important enough for us to apply the same lessons as Fichte taught. The fact that our chemical industries were in such a backward state, with certain exceptions of those which needed least thought and least study and least knowledge, was grave enough, if, as he said, it was due to our national faults—it was grave enough for us in these days to rouse ourselves as the Prussians did rather more than one hundred years ago. He was quite sure that if we did do it the same result would come—that we should regain our position, and regain it even with more glory than it possessed before. There was a time when in no industry could England look on other nations as its superior. Now, in the chemical industry — by which he meant mainly the organic chemical industry—it was all but insignificant, and he read with very bitter feelings an address of one of the ablest industrial chemists in the world, the head of the German chemical industry, who was talking about the very subject, and who said: "England talks now of not only holding her own in war, but beating us in our chemical industries. She cannot do it, and that is because the nation is incapable of the moral effort to take up an industry like that —which implies study, which implies concentration, which implies patience, which implies fixing one's eyes on the distant consequences and not considering merely the momentary profit." When he read those words he asked himself, Was that not a fair judgment for a foreigner who could not know the resources of the English people in the way of repentance and resolution and reformation? Was it not fair for that gentleman to say that our behaviour during all these years showed that we were incapable of doing it? And he (the Chairman) would tell them frankly, that if we did not take the lesson to heart at the time of this war, and when the war had passed — when, as we believed, we should have severed ourselves from the military domination of Germany—resolve to save ourselves from industrial domination, all he could say was that the victory of Germany, if not in the form that it would desire, would be quite as great as it could wish.

[Lord Moulton then left the meeting, and the chair was occupied by Dr. W. H. Maw.]

The paper read was—

BRITAIN AND GERMANY IN RELATION TO THE CHEMICAL TRADE.

By William Reginald Ormandy, D.Sc., F.C.S.

The subject which we have to discuss to-night is not by any means a new one. The fact that Germany has slowly but surely been gaining control of the greater part of the chemical industries of the world has been brought home to this country times innumerable during the last forty years. It is true that this control has not extended to the manufacture of what are known as heavy chemicals, where questions as to the cost of raw materials, fuel and freight are of deciding importance. The present unhappy state of Europe, causing a shortage of many drugs and chemicals, has brought this control home in an unmistakable way to the public, who have been made to realise what the manufacturers have known and ignored for at least a generation. Needless to say, there have been many meetings to discuss the situation by those more or less directly affected. The Society of Chemical Industry, both at their headquarters in London and at several branches, have dealt with the matter, and Dr. Mollwo Perkin has recently read a most interesting paper on the "British Artificial Colour Industry" before the Society of British Dyers and Colourists. I labour, therefore, to a certain extent, under disadvantages, particularly as this manuscript had to go to press before I had an opportunity of learning the particular aspect of this important subject to be touched upon in the paper read here last week by Sir William Tilden. From a conversation with Sir William Tilden it was possible to gather that there was bound to be a certain amount of overlapping, but the general feeling seemed to be that the subject was of sufficient importance to justify a little redundancy, which, at the worst, would only serve to emphasise the need for action. Needless to say, numerous committees have been formed

by all sorts of societies and groups of people more or less directly interested. To the lay mind such committees are places where people go to recite speeches, and they naively assume that the speeches are useful and have a purpose. This is quite a usual conception of a committee; many committee men share it. In times of stress such as those through which we are living, it is increasingly difficult to consider such questions as the one before us to-night from a detached and abstract standpoint. Within the bounds of this ancient Society, which has done so much directly and indirectly for science and industry, which has taken the best that could be offered by people of many nationalities, we can at least endeavour to remember that the marvellous and complicated structures of science and industry are international, that in their essence they know no country; that they stand or should stand as one indissoluble link binding all humanity into one great whole. Attempts, and I think foolish attempts, have been made to allocate to various countries the services which they have rendered to this particular aspect of the progress of humanity. It seems to me quite impossible, even if it had any value, to attempt such allocation. Pure science and industry are so interwoven in as far as they make for material progress that they cannot be considered apart. The apparently unimportant pure scientific discovery of to-day becomes the great corner-stone of an industry to-morrow. Those who adapt scientific discoveries to industrial use are as entitled to honour and reward as those who made the original discovery. Just as the progress of pure science is largely limited by the nature and accuracy of the instruments available, so industrial progress is limited by the nature of the machinery available. Those who discovered the spectroscope little thought of the enormous field of investigation to be opened up by it; those who discovered the possibility of making fire and acid resisting vessels of pure silica rendered possible manufactures which the lack of such vessels had hitherto prohibited. The immediate material benefit derivable from the discovery of new means of industrial attack may far outweigh that from theoretical discoveries which have cost infinitely more of attainment. At a recent meeting of the Society of Chemical Industry in London, where some of the views put forward were characterised as puerile in a chemical trade paper, one speaker referred to the futility of looking at the past, as the present was decidedly a time for action. This is a characteristically British attitude. The time for taking action is exactly the time when the closest regard should be paid to the warnings and lessons of the past. The laws of cause and effect which are studied so earnestly in matters scientific, apply with equal certainty to the more complex relations of human economics. A study of the patent literature of this country would be more than sufficient to convince anyone of the reckless manner in which the literature of our own country is neglected. This being the case, it need not surprise us to find that the scientific and technical literature in foreign languages seldom receives consideration.

We will, then, presume to ignore the advice so proffered, and will take a rapid glance over the progress of scientific and industrial development in Germany and at home. It is probable that the laws relating to the influence of environment, which have been proved to be so important in the animal and vegetable world, will be equally applicable to the development of industries, save that influences, such as national temperament, education, and financial relations of a complex nature, have to be brought into consideration. Industrial development on a very large scale was first rendered possible by the introduction of the steam-engine as a power generator and the provision of adequate means of transport. At a period during which this development was taking place here, the rest of Europe was in a sufficiently unsettled state to permit of this country, without serious opposition, becoming the workshop of the world. No finesse was required to sell the output of our mills and our ironworks. America, like a healthy growing child, had an inconceivable appetite for all those finished and intermediate products which could only be produced by a nation whose industries had been slowly developed and well established. In those days the English manufacturers, who paid low wages, and exacted long hours, made enormous profits. The experimenting which had to be done to develop the various industries was of a rule-of-thumb character and essentially non-scientific in its nature. Probably no nation is so well fitted as the Anglo-Saxon race to develop rapidly along such lines. As a race our people are practically inclined, and so long as development required nothing more than the close application of a healthy common-sense, progress was astonishingly rapid. A very old man, whose family was one of the earliest to take up the manufacture of cast steel in this country, has told me that in the early days of the firm's history it was no uncommon thing to receive orders for

tons of steel required for the manufacture of drills and tools to open up the virgin wealth of America, in which not only was no price mentioned, but it was explicitly stated that within the bounds of reason quick delivery would compensate for any price. The products of our boiler yards were famed throughout the world, and incredible profits were made by firms whose successors have found the competition of recent years more than they could support. This was, of course, due to the fact that in the days of prosperity the profits were divided to the last penny, the machinery was allowed to get out of date, and the working people refused any longer to play the part assigned to them by the manufacturer in his profit-making schemes. Dr. Mollwo Perkin has probably given the correct explanation for this pronounced tendency of British manufacturers to starve and bleed their own business. The rapid industrial development of foreign countries called for enormous capital for railways, shipping, docks and harbours, and the opening up of mining and agricultural properties, and it was felt that a better return could be obtained from such ventures. English spinners and weavers were supplying the whole world with their products, while loom and mule machinery makers were working day and night to supply these foreign purchasers with the machinery for their infant industries which were in future years to compete with the home country for their own and neutral markets. For close upon 100 years the tide flowed in our favour. There was no necessity to practice economy. Nature had been lavish with our raw materials, our insular position and the proximity of our manufacturing centres to the sea-board gave us natural advantages which, added to a favourable situation in international relations, rendered the growth of our material success inevitable. To the thinking mind, it was obvious that such a concatenation of favourable circumstances could not continue indefinitely. We provided other countries, at great profit to ourselves, with all the means necessary for competing with us in those markets in which we had hitherto enjoyed a practical monopoly. Our own works were frequently equipped with out-of-date machinery, which was busily employed in making more modern plant which was put into the hands of those who realised that they would have to exert their powers to the utmost if they were to gain a fair share in the barter of the great international bazaar. The British industry of to-day is in the position of a son inheriting an established business, and having in addition a very large income derived from the labours of past generations. Properly used, such a situation should make for enhanced prosperity; but even such powerful advantages may be nullified if the effort to work along the lines which proved successful in our grandfathers' days are continued too long. Capital directed by ignorance and apathy cannot hope to compete for ever against the forces which are brought to bear to-day.

The industrial life of Germany may be said to have commenced little more than a generation ago. To all intents and purposes an inland country, with little sea-board, they were under a huge disadvantage in every department which required raw materials obtained from abroad. In many directions their natural resources were comparatively poor. They had no iron ores which were comparable with the hematites of Cumberland, their limestone was largely dolomitic, their coals were for the most part poor in quality, and lay often in distorted seams, more like those of our Bristol coalfields than the comparatively easily-worked deposits in our northern area. It was recognised at an early period in their industrial development that national progress in a country situated as was their own could not be left entirely to individualistic effort. Nationalisation of railways and canals became an obvious necessity if differential traffic rates were to be allowed, and differential rates were an absolute necessity if large industries were to be developed in the interior of Germany far from the sea-board. Too much credit cannot be given to the far-sighted way in which every problem of agriculture and industry in Germany is regarded from a national standpoint. It is realised by everyone that individuality must be, to a certain extent, fettered for the benefit of the nation as a whole. In this country individuality runs rampant, and except in times of stress, such as those through which we are passing, the national or Imperial bearing of any individualistic action receives not the slightest consideration. The very people whose fathers sold land to the railway companies at absurdly inflated prices now complain that, owing to the high railway freights in this country they cannot make adequate profits from the investment of the money obtained from those same companies by an earlier extortion. No doubt many of those who have made their profits from such action would like to see the English railways nationalised and freights reduced at the expense of that patient beast of burden, the British

public. Whereas Germany is continuously developing her network of waterways, we in this country, with a customary lack of national forethought, allowed our waterways to become controlled by the railway companies.

Having thus settled the enormously important question of transport, Germany had to consider the lines along which she should seek for an expression of her industrial destiny. Agriculture, there as here the largest individual industry, received attention which is as striking as is the lack of it in this country. Proper afforestation schemes were rendered compulsory; enormous areas of land fit for little else were put under potato cultivation, and science was called in to help to create a new outlet for the crops. Germany became essentially the starch, glucose, and alcohol producing country of Europe. Other large areas were used for the cultivation of the beet, and once again science was called in to assist in the disposal of the roots as raw materials for the production of sugar. If the manufacturing of iron had to become a great industry it was necessary to develop economic methods for the utilisation of the great deposits of low grade phosphatic iron ores which were those chiefly available. In addition to the home deposits of iron ore large amounts have been imported, but how successfully the problem has been tackled is shown when we consider that twenty years ago the German production of iron was a mere fraction of our own, whereas to-day the German output exceeds the British by nearly 100 per cent. The problem of working up the complex metallic ores has fallen almost entirely into German hands. They alone were willing to spend the time and money necessary on researches pertaining thereto, and they alone seemed willing to devote that close chemical skill and attention which is necessary in dealing with these complex problems. In the early days of the chemical industry it must have been quite evident that Germany could not hope to compete in those branches of heavy chemicals such as soda ash, caustic soda, sulphuric acid, bi-chromate of soda, alum, etc., where cheap raw materials, freights, and cheap fuel play a greater *rôle* than chemical skill and complex machinery. There is, however, not the slightest doubt that Germany realised years ago what this country has not yet grasped—namely, that all industrial development tends to become more and more scientific. The adequate utilisation of the by-products from an industry may settle the question of the survival of the industry itself.

The necessity for broad co-operation in great industrial problems was recognised and acted upon in Germany in a hundred directions. By-product recovery coke ovens were installed in the immediate neighbourhood of the blast furnaces, and the surplus gas from both was used for power generation. The steel works were erected in the immediate vicinity of the blast furnaces, so that the surplus power might have an economic outlet. Where it was impossible to bring the steelworks to the vicinity of the coke ovens and the blast furnaces, the surplus energy from these was transmitted far and wide in the form of high-tension electric current sold at an astonishingly low price and thus tempting to the introduction of new small industries within the immediate area. The by-product recovery coke ovens were required to another end. Slowly but surely Germany had been developing her fine chemical industries, drugs, and dyes. Many of these manufactures were dependent for their raw materials on products only obtainable in quantity from this country. We have been building up an enormous industry, not only in the spinning and weaving of cotton and woollen yarns and fabrics, but a correspondingly great industry in the bleaching, dyeing, and finishing of these products. This has been chiefly developed on dyes obtained from Germany, but while we have been content to leave ourselves entirely in the hands of others, the Germans have, by the exercise of scientific skill and a sensible use of capital, rendered themselves independent of this country. German capital was spent like water to foster the development of by-product coke ovens and in the development of the allied fireclay trade for the production of suitable apparatus, to the end that fifteen years ago practically the whole of the hard coke produced in that country was made to give up its toll of by-products which were the raw materials for their great chemical industry. It was in Germany that the preliminary treatment of low-grade coal to render it fitted for the manufacture of a suitable blast furnace coke had its origin and development, and only in the last few years have our colliery companies recognised the value of adequate sorting and washing plant in connection with their output.

The history of the growth of the phosphatic manure trade was a striking lesson in German adaptability, but the time at our disposal will only permit of attention being called to it.

In the whole history of human development, perhaps no trade has varied less in its methods

than that of the potter, and so long as this manufacture depended primarily on the proper utilisation of raw materials as found in Nature and great personal skill on the part of the work-people, so long did this country control the industry. Favoured to an extraordinary degree by Nature in the provision of the necessary raw materials, our work-people developed an almost unnatural skill for the production of beautiful objects under the most adverse conditions and with the most primitive mechanical help. The discovery of the possibility of casting complex forms and the growth of the electric industry with its great demand for porcelains of high insulating capacity, opened the door to German competition, until, before the war, it could be said that the world's demand for electrical porcelain was practically met by Germany alone. The sanitary ware trade has been for many years, in Europe, an English monopoly, probably largely owing to the lack of suitable raw materials in other countries, but by an expenditure of hundreds of thousands of pounds this situation has been changed, and had Germany, at the command of its military dictators, not entered upon this war, I am confident that the control of this industry would have fallen into German hands in the very immediate future.

At the recent meeting of the Society of Chemical Industry above referred to, Professor Henderson referred to the chemical industries of Germany as being merely the development of the crumbs from the British loaf with which they had had to content themselves. In so far as the metallurgical industries are of necessity chemical industries, the term crumb, as applied to an iron and steel trade much greater than our own, seems out of place, and the remark is only another unfortunate example of the willingness that exists in many quarters to pander to an already too strongly developed feeling of national self-esteem. The British as a nation never show up so favourably as when they are placed face to face with difficulty. As a race we have so much of which we can be genuinely proud that it is a little less than treason when those to whom the people should look for guidance and warning feed them with fulsome flattery and lull them to continued sleep with mental opiates. In ever-increasing degree, both in this country and Germany, the population are dependent on industries for their livelihood. Both countries have long passed the stage at which their home market is capable of keeping the industrial machine in full activity. In addition to each being the other's largest customer, both have to look to the rest of the developed parts of the world for an additional outlet. Someone has said that a nation gets the newspapers it deserves. Judging by what has appeared in some portions of the daily press during recent months upon the subject of German trade, it is devoutly to be hoped that the common-sense of the British nation will not be judged thereby. During the past ten years a nation of over sixty millions has been increasingly occupied in industrial operations. Our own smaller population has, on the whole, been equally fully employed during the same period, and yet people write as though there was a possibility that a large proportion of the activities of the larger nation could be profitably undertaken in a small country whose work-people have been for the most part well and profitably employed for the last decade. The absurdity of this requires no refutation. Indignation is expressed at the discovery that German people and German capital are by way of controlling an ever-growing number of industries in this country. I have not seen that any serious attempt has been made to the much more serious end of discovering why the Germans should desire or should be able to get such a foothold in this country. In some few instances I could supply an answer from my own experience. We have already seen how the German Government bring science and agriculture to work together in afforestation, and the cultivation and utilisation of potatoes and beetroots, but throughout the German national history the government have recognised that, as a people, they are in ever-growing degree forced to live on industry, and that modern industry is built on the hand-in-hand co-operation of science and capital. This country is dependent upon industrial development for its very existence in a higher degree than Germany, and yet so far as governmental assistance or interest is concerned the principal occupation of the British people might be the signing of dividend coupons. The German government is incomparably poorer than our own, and yet the financial assistance which they render to technical education is immeasurably greater. The standard of general education is undoubtedly higher, no doubt largely in consequence of the temptation offered by their one-year service system in the army to those who have passed a certain high standard of efficiency. In a land where the standard of payment is, on the whole, much lower than our own, the leading men of German technical schools are far better

paid than in this country. The heads of the technical school staffs are encouraged to become acquainted with the latest technical progress. It is fully realised that a purely academic teacher cannot turn out first-class technical men. The technical industries instantly claim, at higher salary, the members of the staff of technical colleges who have carried out original investigations which seem likely to open out industrial possibilities, and it is not an uncommon thing for such a man to be reclaimed by some technical institution at a later date at a still higher salary. It is realised that the right man, who has works experience as well as technical knowledge, is worth far more to the nation as a teacher than in a private capacity. If an industry requires to make use of ingredients such as alcohol and ether, which are under excise control, the government will go to the greatest trouble to arrange matters in such wise that no needless restraint is imposed. That the staff of a government department should interpret a government order in an unduly restrictive sense, so that an industry might thereby be hampered, is there inconceivable. Only in Great Britain and Turkey are government restrictions allowed to be interpreted at the will of the permanent officials. I do not for one moment wish to imply that I consider that the question of industrial alcohol has been of the main, or even of serious import, compared with others, in our neglect of the fine chemical industries. I quote it rather as an example of the contemptuous attitude which our government has hitherto adopted towards matters industrial. In certain branches of the chemical trade it is essential to have the chemically-pure alcohols and ethers, but the would-be manufacturer is told, by the Government, in effect, that he is not to be a judge of what is necessary, but that the question will be settled by some heaven-sent genius in their permanent employ who, like the journalist on a halfpenny paper, knows more about the subject than the man who has made it a life's work.

A feature of the German industries is their willingness and ability to work in co-operation, as is shown in many ways which are no doubt familiar to most of you, but with which we have not time to deal. With all the help which a favourably-inclined government could render, the German industries would have been unable to approach their present standard of efficiency had it not been for the remarkable co-operation which takes place between science and capital. This can perhaps be best illustrated by means of some concrete examples. Let us suppose that some chemist in Germany has discovered a new and cheaper method for making some chemical product which is in considerable demand, or which might become a large article of manufacture if the price were sufficiently low. If the manufacture is likely to require a considerable capital the inventor would probably go to one of the large banks. The German banks permanently retain the services of some of the leading authorities on a wide range of subjects and the inventor would be asked to put all his case before the particular expert in charge of his department. If the report were of a sufficiently satisfactory nature on the scientific side, the bank would proceed to make their own inquiries, through the many channels open to them, as to the probable outlet for the new product. If the outlook were in all respects sufficiently satisfactory, they would advance the necessary capital at a reasonable rate of interest, making certain stipulations such as that the business should be carried through their bank; that payment for the finished products should be made through the bank; that no contract for the sale of the finished product should be made with any firm without their consent. The bank having much greater facilities for gauging the financial standing of the purchasing public, in this wise protect their own interests and that of the inventor. We have presumed a case in which the investor has a process which is worked out to commercial finality, and capable of being demonstrated to an adequate extent on an experimental scale, but the activities of the German banks do not by any means cease at this point. An inventor may have made certain discoveries in a new, or recondite field of work which, on the small scale, or with the facilities at the disposal of the inventor, cannot be demonstrated commercially, It may only be possible to show that with the expenditure of considerable capital and much labour and time can great results be expected. If the new discovery adumbrates great commercial possibilities, such as the development of a new industry, or means for obtaining control of an existing one, then the banks are willing to give assistance on very reasonable terms.

Naturally, in the latter case the bank makes the most stringent investigation by means of their own experts and by calling in the aid of any of those likely to be best qualified to help in coming to a decision as to the probable economic value of the principles foreshadowed by the new work. The committee of experts

may say that what has been put before them is a new invention; that it seems to open up possibilities that by its help certain great industries of worldwide importance, at present carried on by slow and expensive means, may be entirely revolutionised, and that which took days may be done in minutes, or that which employed expensive materials may eventually be done by employing cheap residual products. They may admit quite candidly that, although all this is likely, it is none the less problematical; but still, in their opinion, a few years' work, and the expenditure of £50,000 or £100,000, will, highly probably, place the owners in a situation which will enable them to exact very great returns for their outlay. The writer knows of a very apposite case where a company has been formed with a capital of nearly half a million sterling to develop certain inventions which in many directions were very embryonic. Practically the whole of this money has been provided by private and other banks, who realise that quite a number of years may elapse before an adequate return is gained, but they also realise that, so far as human skill and knowledge can foresee, a few years will place them in a position to control several of the world's greatest industries, in which case their return will be of a very high order.

Again, nothing is more startling to the Englishman than the ease with which one can gain admission to those in command of the great industries. The directors of the German companies, for the most part, and the managing director invariably, are men of high technical skill in the business they control. The idea of putting a stockbroker or a retired army colonel at the head of a scientific industrial concern would be regarded as an act of madness. Not only are German businesses run by men who understand them, but these industrial leaders have always time to give adequate consideration to any new proposal which is brought before them. It would be the exception rather than the rule to find directors in an English company who were capable of appreciating, still less of judging, the merit of a technical point relating to their own business. It would be almost an impossibility for an unknown outsider to obtain admission to such directors, and even if the unknown inventor succeeded in getting within the veil which hides the holy of holies, it would probably be to find that the master-mind had so many appointments that he never by any chance had time enough to consider any proposal thoroughly. The heads of a German concern have always time to look thoroughly into anything which interests them; they are sufficiently technical to realise the necessity for going into details, a works' experience having taught them that it is on details that great processes come to grief. In spite of their intellectual and commercial attainments, however, these directors are, in some respects, both modest and unassuming. They still think that success can be purchased only at the cost of labour; they are content to work from 8.30 to 6.30, with two hours' pause in the middle of the day, and they work full six days to the week. No doubt they envy, but they do not lay claim to, that super-type of intellect which, labouring hard from eleven till four with an interval for rest, sometimes even five days a week, expects, not only to retain its old position, but to dispossess its competitors; they even learn foreign languages so that they may profit by the knowledge gained by other people in other countries.

Let us suppose for one moment that it was Germany that was short of drugs, photographic chemicals and dyes, and that England had possessed a monopoly in these products. Further, we will suppose that the joint general manager and head chemist of one of the large English drug and photographic chemical works had found himself in Germany at this period, with sufficient acquaintances in that country, men with whom he had for many years made large contracts and who were fully cognisant of his scientific and technical ability to guarantee his claims. He could go to any bank and say, "I can show you how to make a number of photographic chemicals and drugs even more cheaply than they can be made in the country which has hitherto controlled the manufacture, because you have the necessary raw materials, because you have, indeed, previously sold these raw materials to the previous makers. I bring you the necessary evidence that these products can be made at half the sales price obtaining before the war, and I can demonstrate that the sale in your own and neutral countries of these products amounts to some thousands of tons per annum, and that, under normal circumstances, after the war is over, it will be impossible for your business to be displaced by undercutting. Finally, I will bring you reputable dealers who will make contracts for hundreds of tons of these products at prices which will pay for the plant and show profits in one year's working." The bank would confirm these statements through their experts, and probably

within forty-eight hours all the money that was required would be available at 7½ per cent. The man who possessed the scientific, technical, and commercial knowledge would thus be enabled to build up a business which would be profitable to himself and valuable to the community, the fact being that it is recognised in Germany that capital is entitled to a fair return and nothing more.

Now let us imagine that circumstances were reversed. It would require the pencil of a Hassall adequately to depict the scene in the board-room of an English bank where such a proposal had been made. One can imagine the possessor of such knowledge offering it to existing chemical works. Being presumably a travelled and educated individual he would realise that our so-called chemical works were, for the most part, of the tub and stick order—that is to say, that the bulk of their business consisted in acting as agent for German and other firms, and for the rest, recrystallising products or mixing up weed-destroyers. He would discover, if he ever got a hearing, that the larger chemical works, cognisant of the mental attitude of the financial classes in their own country, would either refuse to put forward the necessary capital or would offer to undertake the manufactures on utterly impossible terms. Everywhere he would make the, to him, astonishing discovery that no one realised the possibilities of the industries which he wished to develop. Drugs and photographic chemicals were sold in ounce bottles. If he endeavoured to prove that the total trade in photographic developers was in the thousands of tons per annum he would be met by polite incredulity. Eventually we may suppose that our hero decides to test his fortunes in that great hub of cash, intellect, and roguery—London. Guided by past experience he would probably manufacture a few of the products under the observing eye of the finest independent expert he could learn of, in a country practically ignorant of the industry which he represented, and he would obtain from men of standing the offer of contracts for tons of the materials he proposed to manufacture showing very great profits. If a stranger to the city, the odds are a hundred to one that he would fall into the grasp of some plausible tout of a third-rate company promoter, in which case, unless we are in for the second edition of a thirty years' war, his chances of arriving at any finality are practically nil. The best that he could hope for would be to become a tied servant of a heavily watered company, short of working capital, loaded down with preliminary expenses, weighted with directors and a staff, not only ignorant but careless as to the future of the concern. The amount that he himself might hope to receive from this last and greatest evidence of twentieth-century progress, a city company promotion, would be little else than paper. He would learn that the cash consideration exacted from the British public on the strength of a prospectus backed by guinea-pig directors was required, as to the greater part, to pay commissions to a long train of intermediate parasites who live in this wise on the spoliation of industry.

If by a miracle he succeeded in escaping the clutches of the type above described and was brought into direct touch with real capitalists, he would learn in a practical way the immense respect exacted by English capital, and would be astonished to find that as a representative of creative and productive industry he was to be treated as a lower organism which should be devoutly thankful for being allowed to commune with less intellectual, but socially enormously superior beings. He would find that these worthy representatives of the golden calf had no time to go into details. Having assured themselves that there really were considerable prospects of large financial returns, the last thing they desire is to permit the inventor to put himself in a position to demonstrate the full value of what he is selling.

Whatever certainty attaches to the processes of which he is a master, he must be made to feel that they are nothing more than a vast experiment. Having a positive contract, let us say, for forty tons of a special product showing profits of 3*s*. per lb., and having demonstrated by means of an independent expert appointed by themselves that he can make this product at something like 1*s*. per lb., they will probably offer to find him a very inadequate capital, for which they will require a stiff cumulative preference interest and the bulk of the profits remaining beyond that. In his own country, where salaries ruled lower, he would have received at least double the salary that he will now be offered. No doubt the wanderer from another country would think these terms sufficiently onerous as they stood, but he has yet to learn that in a hundred and one ways his diminished rest of the profits had to run the gauntlet. At the wisdom of the directors other chemists can be put in over his head. For what is a man a director if not to find comfortable berths for striving relatives? The men of gold will employ

a learned advocate, who will draw them up memorandum and articles of association most cunningly worded, whereby, should the occasion warrant it, they can issue shares at a discount, or bring out new classes of shares having prior rights; where they can, in effect, render it practically impossible for any serious proportion of the profits to wander in undesirable directions. Should the inventor have the temerity to suggest that such terms would be hard if applied even to untried inventions which had still to live through that development period where childhood's diseases are active, recourse would be had to the awful effects of example. The ocean of commercial history is foul with the carcasses of dead and gone companies for exploiting chemical and quasi-chemical inventions, and one or more of these would be gibbeted for his benefit. Of course, he would not be given time, even if he had the necessary knowledge, to find out whether the company in question failed because the process was intrinsically bad, or whether, which is much more likely, it perished from that frequent disease of modern limited companies—water on the brain, or rather water in the shares. In my humble opinion the modern company law, with its attendant train of parasitical followers, is more responsible than anything else for the failure of scientific industries to advance in this country. The longer I am acquainted with the men who are something in the City, the greater is my respect for the workers of the North. Just before the war broke out I had almost completed negotiations whereby it would have been possible to introduce selected British inventions to a powerful group of German capitalists. It had long been obvious that it was a waste of time and energy to endeavour to get these, even intelligently, considered by English manufacturers or English capitalists. It proved possible to do more business in this direction in one week in Germany than in this country in a year. In many cases the German capitalists insisted upon having the right to acquire the English patent along with the German. They knew that England was a great market and much the finest centre for building up an export trade, they also knew from past experience how small were the chances that they would have to meet any competition in this country. They had found, from past experience, that it was useless offering their own inventions on this side of the water, and in a large and ever-growing number of cases, convinced of the great value of the processes they were exploiting, they actually bought controlling interests in English companies in order to be in a position to force these to take up new methods which were vital to the progress of the industry in question. If a German discovers a new method for increasing the yield and cheapening the cost of a chemical substance which is an intermediate product in the manufacture of other intermediate products eventually used in dye-making, we cannot take on the manufactures ourselves, for it is valueless. Our chemical works are so far undeveloped in certain directions that they have no use for such a product. It is about as useful as an improved watch escapement would be to an Esquimaux. If the German starts a work in this country for making this and other products, or if he purchases a controlling interest in a firm with the object of compelling its manufacture we complain of German dominance in our industry. The German commercial man was likened in this room to a burglar, and this because he visits our manufacturers in the middle of the day and finds them asleep. Modern commerce is warfare, and the weapons employed are—inventions, tireless industry, skill, and capital. We make the mistake of putting the last first. Those who do research and make inventions, whether in chemistry, engineering, or any other branch, are the yeasts which leaven the whole mass, but in this country we do not allow those conditions of warmth which permit the yeast to work. Gold in itself is not nearly so valuable a metal as iron, and we are slowly but surely finding out that capital itself is an over-valued possession if it be not used for the benefit of the industries and consequently of the nation as a whole Our men at the front in defence of British honour and British security are risking their lives, but the English capitalist has no desire to risk anything. Having, through his own sloth and apathy, through his unwillingness to look ahead, through the inability born of ignorance to appreciate the right use of science, fallen behind in the race he now desires protection. He would persuade the British people that representative government means government of the people, by the people, for the benefit of the—manufacturer. He is a veritable dog in the manger. He refuses to take up new processes or to apply new methods, and objects still more when others, with greater enterprise, seize the opportunity. If the greatest war, if the greatest opportunity this Empire will ever know will not move him to action, I am not so conceited as to imagine that any dialectic weapon which I can wield will be sharp enough to penetrate his hide-bound self-complacency, still less the triple brass of his imagined self-interest.

DISCUSSION.

Sir William A. Tilden, D.Sc., F.R.S., in opening the discussion, said he had listened with mixed feelings not only to the paper but to Lord Moulton's remarks. He could not help hoping most sincerely that the words which had been used by so eminent a person as Lord Moulton would find an echo in those regions inhabited by the leaders of British industry; for it appeared to him that unless a good many of them first of all were brought to acknowledge their position of humiliation, and secondly, determined that if they were too old themselves to learn, at any rate their sons and successors should be taught what was necessary in the way of scientific instruction connected with their own businesses, then it was all over with British industry. He must say out of his own experience, living as he had for fourteen years in a great industrial centre, that many of the author's pungent remarks were really not exaggerated. He used to see, with great regret, young men driving to business in the morning at eleven o'clock when the works had been going from six o'clock. In many works which he had visited he invariably was amazed at the extraordinary ignorance displayed on the part of the partners themselves in the operations which they were supposed to conduct in their businesses. Over and over again he had been in works in the Black Country, and his friend, the director or manager, was exceedingly anxious to show him anything, but if he asked any question about details the manager or director could not answer them, but sent down the yard for "old Tom" or "old George," who was the only person in the place who seemed to know how the process could be conducted. He did not believe that the serious character of the question of education had yet been completely realised by the present industrial directors and leaders, and he could not help thinking that that was one of the most important considerations to be taken into account at the present time—that the young men who were to be the manufacturers of the future should have a very different kind of career from that which had been hitherto prevalent.

Dr. M. O. Forster, F.R.S., said, whilst fully agreeing with the author in his castigations of the manufacturer and the Government, yet he did think that while chemists were so busy in casting motes from other people's eyes, there was one beam in their own which certainly should be removed forthwith, and he thought the present opportunity was the right occasion to remove it. They had too long allowed confusion in the public mind as to what really chemistry was, and what chemists did. It was perfectly ridiculous that any attempt whatever should be made to capture German trade while the general public had not the faintest idea of the difference between the chemist and a druggist. He referred to an advertisement published in a well-known evening paper a short time ago, in which a certain firm of chemists advertised that they had 800 chemists in their employ. It was a ridiculous statement to make; yet, as the law at present stood, it was perfectly true. At the present time the only people who were entitled to call themselves chemists were those who had undergone a course of training at the Pharmaceutical Society or who had passed examinations conducted by that body. In fact, he believed, of all the chemists, so-called, present that evening, only Sir William Tilden was entitled to call himself a chemist by law. Only the previous Sunday a distinguished literary man had said to him, while they were discussing the question of capturing the German chemical trade, "Oh, but Blank's, the chemists, are going to make all these things"; and, again, in the hall of one of the City companies, while discussing the matter, a distinguished architect with educated sons, had asked him to tell him the difference between a chemist and a druggist. It might be asked what bearing had such facts upon the question of the chemical industry. It was that so long as the average educated man with educated sons, whom that man intended to put out into the world, had not the faintest idea what chemistry was, and what chemists did, and who, moreover, had lurking at the back of his mind a suspicion that a chemist only occupied his time in selling sponges and tooth brushes, so long would that man refrain from putting his sons into the chemical industry as a profession. In Germany and France chemists and druggists were clearly defined. He believed that if Lord Moulton were interested sufficiently in the matter to approach the Pharmaceutical Society, and pharmacists in general, at the present time of national stress when all classes were making sacrifices, that they would agree that only those engaged as chemists in the chemical industry should use the name of chemists. If Lord Moulton would do that, and succeed in that object, then he would go down to posterity as the godfather of British chemistry, because he would have given chemists their name.

Dr. Rudolph Messel, F.R.S., thought it had clearly emerged that we as a nation had been, so far as new chemical industries were concerned, as blind as a taxicab driver when he looked for a fare and quite overlooked the man who was hailing him. We had everything ready at our hand. At one time there was a great deal of grumbling about education in science. He had been in England for forty-five years, and he could well speak about the enormous progress which had been made in this country as far as chemistry was concerned. There was talent enough, capital enough, raw material—everything. But what was lacking was enterprise. If the talent which was now available in this country was utilised, the industry could do just as well here as in Germany. He had to give one word of warning in

establishing new industries—first of all to be sure that we only took up those industries which we were prepared to defend when war was over.

Dr. F. G. Ogilvie, C.B., said it had occurred to him, while listening to the paper, that the deplorable condition to which the author had drawn attention was not at all peculiar to the chemical industry; it had been observable in a great many other industries. Each had its own special conditions, but there was one condition which was general, and to which he desired to draw attention. There had been a tendency in connection with many individual industries for the divorce of the control of capital from the knowledge and experience required to apply capital effectively. The influence which produced this tendency was partly a social one, and it was one which he was very hopeful the war might do a great deal to correct. It arose in the following way—he looked at it from the observation of two generations of young men, his own contemporaries, and those who were a generation younger than he himself was—a man had done very well, say, in the manufacture of tweeds in a centre where a large tweed industry was going on. His family found themselves very well to do, and were attracted, as young men, much more to field sports, county meetings and things of that sort than they were to the serious study of their own particular business. The net result was, when they came into power they had to work the business not perhaps entirely by "old George" or "old Tom," but by managers, often underpaid and undertrained, who naturally, even when they proved themselves very good men, had not the ready access to the application of capital year in and year out which was necessary to keep the business up to date. He knew many cases where that had influenced seriously whole regions of trade. It had not happened where the sons had followed in the footsteps of their fathers, but had added scientific training to practical experience in the works. In that case there were good, solid, steady-going businesses which were introducing new products just as fast as could be wished. He trusted that the increasing attention which was being given to the serious aspects of life at the present time would prove permanent, and that it might influence this particular aspect of the matter.

Mr. Adair Roberts desired to address a few words to the young men present that evening. Many of the businesses which it was now sought to capture from Germany could be started with very little capital, and a young man could very well start one of such industries in a small way and enlarge it as time went on if he brought his business, as well as his chemical, ability to bear on the subject.

Mr. Walter F. Reid said, at the previous week's discussion, he had ventured to put the question of capital first in the matter, and he again did so on the present occasion. He thought it was quite impossible to suggest that a young chemist, just out of a college or university, could get a large salary unless he showed himself to be worth it. An employer would not look at him as a professor, but as a beginner from the industrial point of view. In fact, he was an apprentice, and if he was not willing to take the salary of an apprentice at the beginning he could not grumble at the capitalist, who opened up to him a very good future of great promise. With regard to some of the industries which this country had lost, he would refer to the glass industry. His own opinion was that we had lost that industry chiefly through the unwillingness of the workers in the trade to allow apprentices in sufficient number. After the production of capital, the next important point was the security of it. He could not put the matter more clearly than it was put by the Institute of Chemistry, which said: "Provided that the manufacturers could be afforded some guarantee of permanency for their enterprise, and that they may have some reasonable assurance that at the conclusion of the war the newly-developed industry will not suffer from foreign competition, hitherto made possible by economic conditions which do not prevail in this country." Dr. Messel had said exactly the same thing. If the capital which would have to be invested in new and expensive plant and in the payment of research workers and other workers could not be secured, then the capitalist could not be blamed for not coming forward. Our workmen and capitalists must be given the same protection as Germany gave to theirs. Our German competitors could then be met on equal terms, and he was not afraid in the least what Englishmen would do then.

The Author, in reply said the object of his paper was that it should form a stone to make some ripples in what he thought had been a pool of complacency, and he thought it had fairly performed its object. The only question which had been raised, which he thought was of serious import, was that with regard to the industries to be taken up. He agreed absolutely with Dr. Messel: We must be most careful in taking up only those industries where we were at least on as good a footing as the Germans were with regard to raw material. With reference to workmen, he had not the slightest doubt that English workmen were better than any other workmen on the face of the earth. He had watched German, French and Belgian workmen, and he thought the English workman was more reliable and could do more work in a day than any other. But up to the present neither the English workman nor the English chemist had been given half a chance to handle modern scientific processes. It was the opportunity to let each of them prove what they could do that had been lacking, and if

we kept our attention fixed to those things where we had the necessary raw material, there was no question about the future, because we would have our own country and all the neutral countries and all our colonies at least, as a market, and surely that was a big enough one.

THE CHAIRMAN (Dr. Maw), in proposing a hearty vote of thanks to the lecturer for his interesting paper, said that personally he had not had any intimate connection with the chemical industry, but he was sufficiently old to remember that the state of affairs which the author had described as existing in that industry also existed in past times in many other industries. He was glad to say that in the case of the engineering trades and iron and steel manufactures the last twenty years had seen a very remarkable advance in the recognition of the value of scientific research, and he hoped the same advance would take place in the chemical industry. Some of the statements which had been made by Dr. Ormandy reminded him of a story which he had heard of the experience of the late Dr. Elger when he was appointed, many years ago, to the Chair of Naval Architecture at Glasgow University. Dr. Elger had thought it desirable to ascertain to what extent scientific research was being carried out at the chief shipbuilding establishments on the Clyde, and he found the results of his inquiries to be very varied. At some places much important work was being done, and at others the commercial value of scientific inquiry was practically ignored. In one instance, when he was informed that a scientific department existed he ventured to ask the head of the firm if he found the work of the department remunerative, and, receiving a reply more or less in the affirmative, he further asked if he might be told how much was spent on the department. The reply was that "he" had hitherto had "sax and twenty shillings the week," but that "he had now got a rise of two shillings"! This was many years ago, and the state of affairs was now very different.

The vote of thanks to the author for his interesting paper was put and carried with acclamation.

THE COTTON INDUSTRY OF THE LEEWARD ISLANDS COLONY.*

In this paper the history of the development of the industry of the cultivation of Sea Island cotton in the Leeward Islands Colony of the British West Indies is traced.

An account is given of the conditions under which the staple is produced in the different Presidencies of the Colony.

The methods adopted to foster the growth of the industry are described, and the manner in which development has occurred is illustrated by statistics giving the detailed exports for each year since the inception of the industry.

The cultural methods in vogue are dealt with and also the means adopted to secure the maintenance and improvement of the staple by means of plant selection: this side of the work has for a number of years past constituted a very important branch of the activities of the Agricultural Department.

The principal insect and fungoid diseases to which the crop is liable are enumerated and the means adopted for their control indicated.

In the concluding sections of the paper the conditions under which the industry is carried on in each of the islands in which Sea Island cotton is grown are summarised in some detail, while finally a general review is given of conditions affecting the stability of the industry and its future prospects.

The natural conditions obtaining in many of the islands are well adapted to the cultivation of Sea Island cotton.

The industry dates from the year 1902, and at present is carried on in Antigua, Barbuda, St. Kitts, Nevis, Anguilla, Montserrat, and the Virgin Islands. It is conducted both as an estates crop and also as a peasant industry.

Development has been assisted by the Government through the medium of the Agricultural Department and by the British Cotton Growing Association. The assistance rendered has taken the form of grants in aid of purchase of machinery, of skilled advice on the treatment of the crop, and of the provision of market facilities.

The soils on which the crop is grown include a very large variety of types ranging fron non-calcareous volcanic sandy loams and loams to highly calcareous soils.

The annual rainfall in the cotton-growing districts ranges from 30 to 70 ins.

The total area at present under cultivation is estimated to range from 8,000 to 10,000 acres annually.

The total exports from the Colony for each year since the development of the industry are given in summarised form below:—

Year.	Exports of lint in lbs.	Year.	Exports of lint in lbs.
1902–3	50,480	1908–9	697,423
1903–4	152,160	1909–10	690,154
1904–5	382,477	1910–11	1,371,307
1905–6	526,382	1911–12	1,078,794
1906–7	702,910	1912–13	1,149,189
1907–8	1,127,126		

* Abstract of a paper read by H. A. Tempany, B.Sc., F.I.C., F.C.S., Superintendent of Agriculture for the Leeward Islands, at the Third International Congress of Tropical Agriculture, London, 1914.

At an assumed value of 1*s*. 6*d*. per lb. for lint it will be seen that during the past three years the value of the exports has ranged between £75,000 and £100,000 per annum, while the total value of the exports for the entire period during which the product has been cultivated exceeds £500,000 in value.

The importance of maintaining the quality of the strains of seed cultivated is very great. Seed of high quality was introduced into the Colony from the Sea Islands of South Carolina in 1904 through the agency of Sir D. Morris, then Commissioner of Agriculture for the West Indies; this has formed the starting-point from which the majority of the strains at present cultivated have been derived. At the present time large-scale selection work is carried out by the Agricultural Department in every Presidency, and many of the strains of seed thus originated have found their way into general cultivation.

For its successful production the crop requires high cultivation, and in this respect the level maintained is, in practically all cases, satisfactory. Hand labour is very largely employed.

Experience has shown that each island tends to develop a type of lint characteristic of itself as the result of local soil and climatic conditions; this fact is of great importance in relation to the origin of strains of seed to be planted each year.

The principal insect pests to which the crop is subject are the Cotton Worm (*Alabama argillacea*), Leaf Blister Mite (*Eriophies gossypii*), Cotton Stainers (*Dysdercus* spp.), and the Flower-bud Maggot (*Contarinia gossypii*), the last only having proved a pest of serious importance in Antigua up to the present. Among fungoid pests must be classed Anthracnose, Angular leaf spot, and a bacterial boll rot. On the whole the insect pests must be regarded as of more importance than those of fungoid origin. In the majority of cases the various diseases and the methods of control are well understood.

Regarding the conditions under which the industry is conducted in the different islands, in Antigua the crop is grown both as a main crop and as a rotation crop with sugar; there is also a certain amount of peasant-grown cotton. The industry experienced a considerable check owing to the attacks of the Flower-bud Maggot disease between the years 1907 and 1909, but has now recovered from this to a large extent. In Barbuda the industry is carried on as an estates crop by the Government, about 130 acres being cultivated each year; the enterprise has resulted in placing the island in a solvent condition; formerly it constituted a charge on the revenue of Antigua.

In St. Kitts the crop is grown very largely as an intermediate between two crops of sugar cane; it is also grown to some extent as a main crop; there is no peasant industry. St. Kitts cotton has now attained a very favourable reputation among spinners, and the industry is very firmly established.

In Nevis cotton is grown as a main crop on estates, and there is also an important peasant industry. The crop has very largely replaced sugar, and has exercised a very profound effect on the prosperity of the island.

In Anguilla the crop is almost entirely grown by peasants, and its introduction has resulted in the restoration of a moderate degree of prosperity to a community which formerly existed in a condition of abject poverty. Mention must be made of the efforts of Mr. C. Rey, who, as a local landowner and the agent of the Local Government and the British Cotton Growing Association, has assisted in bringing about the existing state of affairs.

In Montserrat the staple is very largely cultivated both on estates and by peasants; the crop now constitutes the principal product of the island, and its introduction has resulted in the re-establishment of a considerable measure of prosperity.

In the Virgin Islands the industry is conducted purely as a peasant industry, and cotton is widely grown on numerous scattered small holdings on the collection of small islands of which the Presidency is composed. The crop is purchased and exported by the Government through the medium of the Agricultural Department. Its introduction has resulted in the establishment of a greatly increased measure of prosperity among the peasant proprietary of the locality.

The industry may be looked on as firmly established in the Colony; the period of its development is brief, but in that time it has effected a very pronounced improvement in the economic conditions, and now ranks second in importance in the industries of the Colony. The present position must be attributed in no small measure to the unremitting efforts which have been made to foster development. The future of the industry depends on the continuation of favourable market conditions and on the absence of any wholesale destructive agency which does not permit of ready control.

The history of the development of the industry is of interest, and serves to indicate the steps best calculated to promote the development of other agricultural industries under similar conditions.

CAPTURE OF AKABAH.

The recent bombardment and capture of Akabah, though directed against a Turkish fort of no great fame, is important as dealing with a region of political interest, *i.e.*, the frontier line between Turkish and Egyptian territory, which, as recently as 1906, formed the subject of somewhat acute diplomatic discussions, through the occupation by the Turks of Tabah, a post lying a few miles west of Akabah, and consequently on the Egyptian side of the frontier line. The dispute was eventually settled by the withdrawal of the Turkish troops, who had garrisoned Akabah in force, under the plainest intimation from the British Ambassador to the Porte that unless this were done within ten days Great Britain would take forcible steps to drive the Turks back over the frontier line. The

present situation has been doubtless brought about by German instigation, just as the previous crisis was in 1906; but the recent destruction of the Akabah fort by H.M.S. "Minerva" will probably act as a forcible deterrent, though endeavours are being made by the Ottoman Government to move down troops towards the Egyptian frontier, along the Turkish railway from Damascus to Maan, the nearest station to Akabah. From thence westward to the banks of the Suez Canal the Sinai country is sterile and almost waterless, and thus very difficult for the transit of troops without elaborate preparations for transport. The population of the peninsula is about 30,000, all of Arab origin, excepting the Jebalia tribe, said to be descended from the troops despatched by the Emperor Justinian at the beginning of the sixth century, to defend the Sinai monastery from the attacks of the natives. Akabah is quite a small village, shaded by numerous palm trees, which contrast pleasingly with the rocky surroundings. The village itself is a very poor place, consisting of a few mud huts, but the fort which has just been shelled and destroyed by the "Minerva" is said to have dated from the sixteenth century, and was built for the purpose of protecting the pilgrim route to Mecca. The site is believed to have been that of Elath of the Bible, and perhaps identical with Solomon's port where his ships were built for the purpose of trading with Ophir. Another important feature regarding Akabah is that if the well-known project of a trans-Arabian railway from Egypt to the head of the Persian Gulf, and thence to the Indian frontier, should ever materialise, such a line would pass through or near Akabah and Maan, and thus form an important junction with the Hedjaz railway, which has been constructed for pilgrimage purposes to the holy cities of Islam.

TUNNELLING BY MACHINERY IN THE MARITIME ALPS ON THE NICE AND CUNEO RAILWAY.

The boring of the two principal tunnels on the railway which eventually will unite Nice with Cuneo and Turin by the Col di Tenda is making satisfactory progress. At the Braus, 5,950 metres (3 miles 1,225 yards), which traverses the mountain range that separates the waters of the Paillon from those of the Bevera, and emerges about 1½ mile from Sospel, 4,600 metres (5,029 yards) of heading have been driven, which leaves 1,350 metres (1,476 yards) still to be pierced by the Ingersoll rock drills, which are working from both sides. The piercing of Mont Grazian, which separates the Bevera and Roya valleys, about 8 miles east of Sospel station, is now completed. It measures 3,880 metres (2 miles 722 yards) from side to side. For about half this distance it is under Italian soil, although the two ends from which the boring operations were carried on are in France. Both these tunnels are now being excavated to the full size for a double line of rails, and are being lined with masonry. The motive power used for driving the air-compressing machinery which actuates the rock drills is furnished by the Société d'Énergie Électrique du Litoral Méditerranéen from their power stations on the rivers Loup and Siagne, situated at least 50 kilometres (30 miles) distant towards Grasse. The opening of the new line in about three years' time will shorten the distance between Nice and Turin by about 47 miles, as compared with the present route by Ventimille and Savona. It will reduce the distance from Nice to Berne to only 537 kilometres (333 miles) via Turin, the Simplon, and the Lötschberg tunnels, on which part of the line a direct train service has already been established.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Imperial Wool.—The official measures taken to restrain the export of wool from the British Colonies have two obvious justifications. Supplies of wool are running low in this country, and prudence demands that home requirements should be met even before those of the most benevolently neutral people. Again, wool is indispensable to armies in the European field, and pains are well bestowed in preventing its supply to the enemy. The measures have shown more pointedly than ever before how dependent the wool manufacturing countries are upon the sheep of the British Empire. The gross total figures do not fully illuminate the case. It would seem from them that some three-eighths of all the wool grown is shorn within the Empire, but calculations which bulk indiscriminately fine and coarse wools and include those taken only for local consumption can neither be exact nor highly informing. One is on safer ground in dealing with the commercial clip, or that portion of the whole that is grown in or imported into Europe and North America, and it can be said with sound assurance that of this the Empire furnishes not less than 45 per cent. The quantitative importance is only the beginning of the matter. They are the most select wools, large bulks of uniform quality are available and their properties render them, on the whole, more desirable than wools from any other source. Australian merino is incomparably the chief material for making fine goods, and even the much smaller Cape supply has a niche of its own which no alternative wool quite fills. Although New Zealand crossbred has a considerable competitor in Argentine wool, grown upon sheep of similar strains, it is still the most desirable material for medium goods, for hosiery, and, incidentally, for khaki. The home-grown British wools are of an excellence almost as varied as their breeds, and our special wools are sought for special purposes in every considerable manufacturing country. Their peculiar quality makes the drying-up of all British sources a more

serious matter than might be judged from the comparison of bare figures.

Government Contracts.—The iniquity of army contractors is an article of faith with a wide public, although there has been one at least of whom the English might hesitate to think evil. St. George of Cappadocia was an army contractor in one interlude, and it can be affirmed that in the present the list of contractors to the War Office includes a number of the most unassailable names in the cloth manufacturing world. A current estimate asserts that 250 miles of wool khaki cloth are being produced weekly. Two hundred concerns are working under Government contract and supervision, and all their energies fail to produce cloth enough. Even tapestry carpet looms have been remounted and pressed into the service. Substantially all the looms of which the normal function is to weave fine worsted and woollens are working, to the regret of their owners, upon the difficult khaki. The work is troublesome and tedious, the specifications, as to strength in particular, are almost impossibly high, and the prices paid are not those to which makers of fine cloth are accustomed. It may be believed, therefore, that ignorant charges of villainy are somewhat galling to men who are doing their best and fully satisfying the official standards. As the only buyer the Government has the sellers easily in its power, and the authorities have in addition certain reserves of force. Tolerably plain intimations have been received that the hand of authority is supreme to make and amend prices, to seize material if need be, and to commandeer factories and replace the owners or managers. In these circumstances it is judicious to receive reports of bad materials and workmanship with strict caution.

Cotton Accoutrements.—Cotton has replaced leather in more than a few directions in the past. Bootlaces, handbags, and the realistic leather imitations used for seating afford familiar examples, but it is perhaps the analogy with machine belting that has prompted the new equipment of the private soldier. A broad waistbelt of brown cotton canvas replaces the narrower leather one. The shoulder straps, rucksack, and haversack are of the same material, as are the cartridge belts. The material has been selected with an eye to wear, and the fabrics are made with tightly-twisted five-ply cotton yarn. Doubtless both time and money are saved by the authorisation of this material, and a distinct advantage is possessed by the cotton bandolier. Cartridges can be served ready packed in the belt, saving the trouble of filling pouches on the field, and the old empty belt is cheap enough to be thrown away.

British Dyewares.—The shortage of dyestuffs, having stimulated ingenuity, has led to the discovery of more than one means of widening the scope of the so-called sulphur colours. These have been available hitherto only upon cotton, and have been used especially largely in dyeing black. The dyes resist light, soap and acids well, they are cheap, and made extensively in England. It may not be regarded wholly as a demerit that some dyers call the shades obtained a little flat, like those given by the old-fashioned dyewoods. Messrs. Lodge and Evans, of Huddersfield, have devised one means by which this range of dyes can be used for the animal as well as the vegetable fibres. The colour makers have also been at work, and sulphide dyes are now supplied in a form ready for dyeing wool and cotton in the same bath. The new facility is equivalent to an extension of British resources. Prospectively, at least, British supplies have been further increased by the arrangement of terms for the right to manufacture under German licence. It appears that German holders of English patents expect a royalty of 7½ per cent. upon the net price, coupled with an undertaking as to the minimum quantity to be manufactured.

State-aided Dyestuffs.—Great interest has been taken in the Government proposals for the subvention of a British colour-making industry, but the means of arriving at a fully informed opinion upon them are possessed only by a few. As is the way in all questions of State-aid, there are conflicting opinions as to the policy of giving a twenty-five years guarantee of the debenture interest upon £1,500,000. Some doubts are heard also about the need for an immediate decision, seeing that in any case some time must elapse before a great new factory could be planned and equipped. However, it is not readily to be supposed that these aspects of the question have escaped the large consumers of colour who have been in consultation with the Board of Trade, and unless they had felt seriously inclined to find one or two millions of capital for the proposed undertaking negotiations could hardly have proceeded so far. The chief consumers are, of course, the great combines of commission dyers and calico printers, who are, besides, the largest customers of the German works and purchasers of colour by the thousand tons. They are quite the last people to wish to see colour made dearer in this country, and if, with their sources of information, they are not dismayed at the prospect of the unlimited dumping which some foresee, other persons may take heart of grace. The fear of some parties is that German competition in the future would so depress prices and menace the English colour factory that import duties would have to be instituted to safeguard the interests of the State. If our multi-millionaire dyeing companies commit themselves to the Government scheme it may be taken for granted that they do so after as careful a deliberation as they give to their other investments. To them and to textile manufacturers the manufacture of colour is of secondary interest to its use. A return covering the interest on their outlay would satisfy them, and their knowledge of their own consumption

is such that the prospects of commercial success can be gauged with fair accuracy. Some reasons can be found in contemporary history for refusing to be too much afraid of German prowess.

The Largest Loom.—The largest looms of which this country has any general acquaintance are doubtless those used in weaving seamless carpet squares. On the handlooms for weaving patent or chenille Axminster five men work to pass the shuttle and beat home the weft. But the power-loom that is called the world's largest was built not long ago in Chemnitz for the purpose of weaving felts for paper-making machines. The makers built a loom of 59-foot reed space in 1910, and the new one has a width of 75·4 feet and a shuttle weighing 19¾ lbs. A 9-foot loom being a considerable monster in the ordinary woollen trade the dimensions may be the more appreciated. The loom has been made doubtless to keep pace with the development of paper-making machinery. No statement is made as to the width of the paper machine which the felt is to fit, but it may be apprehended that the loom-width allows generously for the contraction that will take place in course of the felting treatment which the fabric will undergo. Except that the framing is strengthened in proportion to the size, the loom appears to differ little in design from the ordinary. On a machine of these dimensions the reverend inventor of the power-loom might have thought his "springs strong enough to throw a Congreve rocket" less obviously out of place than upon his early model.

GENERAL NOTES.

THE SHORTAGE OF AUTOMOBILE PARTS DUE TO THE WAR.—The difficulties which confront the automobile industry through their past reliance on the Continent for much of the materials of which their cars are constructed, are now enhanced by the fact that all the big steel makers in this country are inundated with orders for war material which naturally must take precedence over all others. The automobile engineer must, however, obtain steel castings, forgings, stampings, and other accessories in order to be able to carry on his business at all, and he is, therefore, obliged to look for some new source of supply. What this source shall be is the immediate difficulty which the Institution of Automobile Engineers is making every endeavour to discover. The first step was the reading of a paper by Mr. L. H. Pomeroy, of the Vauxhall Motor Company, in London, on October 14th (which was printed in the *Journal* of November 6th, pp. 1012-21), but this paper, though it provoked a great amount of interest in the subject, did not provide a solution. Mr. Pomeroy has now been deputed by the Council to make another attempt in the Midlands, and he will read a second paper on similar lines in Birmingham in December. A large number of firms connected with the steel industry, who are already interested in this particular branch of the subject, or who might become interested, have been invited by the Council to be present at the meeting, in order that they may hear the views of the automobile engineer and put forward their own criticisms or suggestions. It is hoped that a large gathering of automobile manufacturers will also be present, so that the whole subject may be thoroughly thrashed out from the two points of view. Full particulars of the meeting and copies of the paper may be obtained on application to the Secretary of the Institution of Automobile Engineers, 28, Victoria Street, Westminster, London, S.W.

HOW TO SUPPLANT THE ENEMY TRADE IN INDIA.—The Indian Commercial Intelligence Department in Calcutta has been considering how best to afford assistance to Indian manufacturers to lay themselves out to produce articles hitherto imported from Germany and Austria-Hungary. The department is accordingly issuing a series of brief memoranda or leaflets on different industries, setting forth statistics of imports, exports, and local production, and other details, including prices and usages of the various markets. It is proposed to supplement these memoranda by an exhibition, to be held probably in Bombay and Madras, as well as in Calcutta, showing samples of certain kinds of goods imported from Germany and Austria, together with samples of similar goods manufactured in India and possibly elsewhere. Samples are already being collected of the following classes of goods: glass ware, enamelled iron and other hardware, cutlery, textiles (especially hosiery and woollen shawls), pencils, matches, and toys. In all of these it is officially considered that there is a clear opportunity of creation and expansion of trade in India.

VICTORIA AND ALBERT MUSEUM.—Mr. J. Lavery, A.R.A., has presented to the Victoria and Albert Museum the portrait which he painted last year of Auguste Rodin. He wishes the gift to be regarded as a tribute to Rodin from British Art. It is designed to reciprocate the sentiments which inspired Rodin to make his magnificent gift of sculpture to the Victoria and Albert Museum, in admiration of the heroism of French and British soldiers who are fighting at this moment side by side. The portrait is almost full length, with the head in profile.

RICE PRODUCTION IN SPAIN.—The Province of Valencia is the most important rice-growing centre in Spain, the average annual crop amounting to some 200,000 tons. Rice, as popular food, enters into the diet of the people to such an extent that the home production is not sufficient to meet demands, and annual imports are necessary. In the Province of Tarragona rice is grown on the right bank of the Ebro River, and in the "Amposta" tract; total production, 29,750 tons in 1913 from 21,004 acres. The Province of Gerona and the Balearic Islands produced considerable quantities.

The two principal varieties grown along the Ebro River are Benlloch and Bomba. Rice-sowing in the Barcelona district is done about the end of March and beginning of April. Harvest begins in August, continuing into early September under normal weather conditions. Much of the work is done by peasants from Valencia, who go to the Tarragona rice fields for the sowing and harvesting.

Reinforced Concrete.—In the course of his Presidential Address to the Concrete Institute, Professor Henry Adams quoted some striking figures to show the progress made in the use of reinforced concrete for bridges. Among the larger examples, he said, we have 233-ft. span in the Walnut Lane Bridge, Philadelphia; 320 ft. at Grafton, New Zealand; 328 ft. over the Tiber at Rome; 330 ft. at Largweiz, in Switzerland—all within 100 ft. difference. Now we have the proposed Spuyten-Duyvil Creek Bridge at New York, where a span of 703 ft. is proposed, or more than double. A steel bridge now under construction in this country for erection across the Ganges is a mile long, in fifteen spans of about 350 ft. each, and will contain 30,000 tons of steel.

Fish Frozen Alive.—Professor Raoul Pictet has been continuing the researches which he described in the paper on "Les Basses Températures," read before the Society in 1911, and it is now possible, according to the *American Journal*, to freeze live fish in cakes of ice, and revive them to their original state after a few months' "cooling." He recently placed twenty-eight fish in a box containing water rich in oxygen, in which several pieces of ice were floating, and then very slowly reduced the temperature. At the end of about two months the resultant cake of ice was gradually thawed, and the fish all found to be alive. It is essential that the water should be very gradually frozen, and that it should have contained pieces of ice for from fifteen to eighteen hours before the whole mass is frozen. The thawing must also be very slow. It is hoped that Alaskan salmon and Siberian sturgeon may thus be shipped alive to Paris.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

December 9.—William A. Young, "Domestic Metal Work of the Eighteenth Century." Professor William Gowland, F.R.S., will preside.

December 16.—Sir William de Wiveslie Abney, K.C.B., D.C.L., D.Sc., F.R.S., "Testing Pigments for Permanence of Colour."

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

December 17.—Dr. F. Mollwo Perkin, F.I.C., F.C.S., "The Indian Indigo Industry." Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., will preside.

Papers to be read after Christmas:—

F. Vincent Brooks, "British Lithography in 1915."

Hon. John Collier, R.O.I., "Portrait Painting."

Octavius Charles Beale, Chairman of the Australian Manufacturers' Association, "Imperial Industrial Development after the War."

Thomas Worthington, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. Thorne Baker, "The Industrial Uses of Radium."

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

G. W. Hulme, "Patent Law."

W. T. Thornton, "The Industrial Uses of Coal Gas."

D. Y. Cameron, A.R.A., R.E., "Etching."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

William Poel, "Shakespeare's Profession."

Arthur Wilcock, "Designing for Textiles."

J. A. Hunter, "The Textile Industries of Great Britain and of Germany."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Edward R. Davson, "Colonial Sugar Development."

Major E. H. M. Leggett, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda."

Henry John Elwes, F.R.S., "Nepal."

Captain Sir George Duff Dunbar, Bart., I.A., "Tribes of the Brahmaputra Valley."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 21, February 18, March 18, April 15, May 13.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

February 2, March, 2, 30, May 4.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

R. A. Peddie, Librarian, St. Bride Foundation Typographical Library, "The History and Practice of the Art of Printing." Four Lectures.

Lecture III.—December 7.—*The 19th and 20th Centuries continued.* Woodcuts of the Sixties

—Invention of the half-tone—Revival of hand-press work for artistic production—Effect of revival on commercial work—Types and Typefounders—Recent inventions in illustration.

LECTURE IV.—DECEMBER 14.—*The later history of colour printing.* Rise of chromo-lithography—Chromo-xylography—The three-colour process—Collotype—Photogravure and its combinations—The offset process.

DR. F. MOLLWO PERKIN, F.I.C., F.C.S., "Oils, their Production and Manufacture." Three Lectures.

January 18, 25, February 1.

M. H. BAILLIE SCOTT, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evenings, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

February 15, 22, March 1.

JUVENILE LECTURES.

Wednesday afternoons, at 5 o'clock:—

H. PLUNKET GREENE, "How to Sing a Song." Two lectures, with vocal illustrations.

January 6, 13.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 7...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. R. A. Peddie, "The History and Practice of the Art of Printing." (Lecture III.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 6 p.m. 1. Annual General Meeting. 2. Professor P. Wrightson, "The Extension of Agricultural Food Supplies."

Royal Institution, Albemarle street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. S. M. Dodington, "Mechanical Appliances for the Painless Killing of Animals."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Professor L. W. Lyde, "Types of Political Frontiers in Europe."

TUESDAY, DECEMBER 8...Naval Architects, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m.

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Professor L. de la Vallée Poussin, "Ma Définition du Grand Véhicule."

Pharmaceutical Society, 17, Bloomsbury-square, W.C., 8 p.m. Discussion on "The Effects of the War on the Nation's Supply of Drugs and Chemicals."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 7.30 p.m. Professor G. S. Woodhead, "Preventive Inoculation."

WEDNESDAY, DECEMBER 9...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. A. Young, "Domestic Metal Work of the Eighteenth Century."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. F. Legge, "The Religion of Manes and the Discoveries in the Far East."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Professor W. Watson, "Benzol, Alcohol and mixtures of these liquids with Petrol as Fuels for Internal-combustion Engines."

British Academy, at the Royal Society, Burlington House, Piccadilly, W., 5 p.m. M. Emile Boutroux, "Certitude et Vérité."

Literature, Royal Society of, 20, Hanover-square, W., 5.15 p.m. Professor H. Newbolt, "Poetry and War."

Royal Agricultural Society of England, Royal Agricultural Hall, Islington, N., 2.30 p.m. Annual General Meeting.

THURSDAY, DECEMBER 10 Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street Adelphi, W.C., 5 p.m. Conference on "The Mobilisation of Credit in War Time."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Rev. D. G. Cowan, "A Visit to Iceland."

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. Presidential Address, "Ophthalmological Instrument Design, with special reference to Accuracy and Rapidity of Working."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. E. B. Wedmore, "Automatic Protective Switchgear for Alternating-current Systems."

FRIDAY, DECEMBER 11...Chadwick Public Lectures, at the London School of Economics, Clare-market, W.C., 8.15 p.m. Sir R. Ross, "Government and Military Sanitation in the Tropics." (Lecture II.)

Malacological Society, Burlington House, W., 8 p.m. 1. Rev. A. H. Cooke, "The Geographical Distribution of *Purpura lapillus* (L.): i. In Palearctic Waters; ii In Nearctic Waters." 2. Messrs A. S. Kennard and B. B. Woodward, "On the Non-marine Mollusca of a Post-Pliocene deposit at Apethorpe, Northants." 3. Mr. L. St. George Byne, "On Monstrosities in *Cypræa.*" 4. Mr. J. E. Cooper, "On Monstrosities of *Littorina rudis.*"

Water Engineers, Institution of, at the Geological Society, Burlington House, W., 2 p.m. 1. Mr. J. C. Barrowclough, "Notes on Scraping a 15-inch Trunk Main at Batley." 2. Mr. C. W. S. Oldham, "The Whitton Pumping Station of the Ipswich Corporation Waterworks."

Correction.—Mr. Alan S. Cole, C.B., asks that the following correction be made in his letter on "Map-making and Tapestries," which appeared in the last issue of the *Journal*:—

In the sentence "The pilgrimage of Otto Heinrich, Count Palatine and Duke of Bavaria, to the Holy Sepulchre at Jerusalem, in 1521, is the subject of a mixed topographical and special, or story-telling design, woven in a large tapestry hanging now in the Industrial Art Museum of Munich" (p. 41, lines 7–12), for the word "special" substitute the word "epical."

Journal of the Royal Society of Arts.

No. 3,238. VOL. LXIII.

FRIDAY, DECEMBER 11, 1914.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK

MONDAY, DECEMBER 14th, at 8 p.m. (Cantor Lecture.) R. A. PEDDIE, Librarian, St. Bride Foundation Typographical Library, "The History and Practice of the Art of Printing." (Lecture IV.)

WEDNESDAY, DECEMBER 16th, at 8 p.m. (Ordinary Meeting.) SIR WILLIAM DE WIVESLIE ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "Testing Pigments for Permanence of Colour." SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, will preside.

THURSDAY, DECEMBER 17th, at 4.30 p.m. (Indian Section.) DR. F. MOLLWO PERKIN, F.I.C., F.C.S., "The Indian Indigo Industry." SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, December 7th, MR. R. A. PEDDIE delivered the third lecture of his course on "The History and Practice of the Art of Printing."

The lectures will be published in the *Journal* during the Christmas recess.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 6th and 13th, 1915, at 5 p.m., by MR. H. PLUNKET GREENE, on "How to Sing a Song."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

Wednesday, December 9th, 1914; WILLIAM GOWLAND, F.R.S., Emeritus Professor of Metallurgy, Imperial College of Science and Technology, in the chair.

The following candidate was proposed for election as a Fellow of the Society:—

Meriwether, Hunter M., 3616, Gladstone Boulevard, Kansas City, Missouri, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Bates, Onward, 332, South Michigan Avenue, Chicago, Illinois, U.S.A.

Bone, Philip James, New Bedford-road, Luton, Bedfordshire.

Fearnley, Ths., Messrs. Fearnley & Eger, Post Box 223, Christiania, Norway.

Otis, Herbert Foster, The Laboratory, Nahant, Massachusetts, U.S.A.

The paper read was—

DOMESTIC METAL WORK OF THE EIGHTEENTH CENTURY.

By Wm. A. Young.

The genesis of this paper may be sought in a review, which was written in 1912, of Mr. F. W. Bradbury's "History of Old Sheffield Plate," itself a monument of long and patient investigation of a bygone metal craft. The author was kind enough to communicate with me after the review had appeared, drawing my attention to a small collection of old trade catalogues dealing with domestic metal work in the late eighteenth and early nineteenth century, which is one of the treasures of the Department of Engraving, Illustration and Design at the Victoria and Albert Museum. It was my privilege a few months later to assist in the preparation of a catalogue of those catalogues. How Sir Henry Wood obtained a copy, and how he traced my connection with it, I cannot pretend to explain, but he did find me, and his invitation led me to prepare this evening's paper.

Mr. Gerald Lee, in his provocative book on "Crowds," wrote: "The things that real people are really doing when one thinks of it, are soap, tooth-brushes, subsoil pipes, wallpaper, razors, mattresses, suspenders, tiles, shoes, pots and kettles." Quite a useful list of articles on which to start housekeeping or shopkeeping; and when you come to think of it, the point of view is at once sane and as old as the hills. The Studley Royal Bowl may become in the course of years the gem of a national collection, or the Ashburnham Salt a priceless addition to a millionaire's museum, but such articles are the super-things of an artistic past A craftsman of Cellini's ability naturally finds his biographer, but the homely worker of the town and country passes away leaving here and there evidence of his craftsmanship, but at best, only some casual record of his name or reference to his circumstances.

If, then, you want to find out what the common people were really making for each other, you must look into your provincial museums, peep into the windows of curiosity shops, and linger on the doorsteps of the older country cottages. It is a matter upon which we, as a nation, may congratulate ourselves that there is growing up a considerable body of collections largely comprised of these objects of everyday use and life. Personally, I know of such museums at Canterbury, Maidstone, Lewes, Brighton, Hull, Ipswich, Hastings, Guildford and Ely. Each has its special features, and all have yielded something to my knowledge of this subject of domestic metal work.

Directly you begin to investigate the by-ways of a bygone craft, certain problems present themselves. Study the subject from the standpoint of social economy, and you are helped by writers like Mr. George Unwin, who can reconstruct the conditions and circumstances of the past on moderately definite and sure foundations. The evidence available discloses the swing of the pendulum between manufacturing interests and capitalistic control. Once in a while the makers of the wares are predominant, but more often, I am afraid, the merchants with money at their command had masters and journeymen alike under their thumbs. We are apt to look upon this matter as involving two interests, labour on one end of the see-saw, capital at the other, with the former, according to the caricaturists, usually in the air. The eighteenth century industrial quarrels, however, were usually triangular affairs, with merchant, employer and journeyman at the corners.

The Practical Side of Bygone Crafts.

If the past story of a craft or group of crafts is studied from the practical side, which is really a somewhat neglected phase, a quite different set of problems is encountered. There are plenty of examples of the work of common workmen, but a very limited literature on the subject. What you can learn of the work must be gathered from the articles available for examination, and if that line is followed certain questions come into mind. Where did the workers of any period turn for a continuous and regular supply of materials proper to their trades? What sort of tools had they and who made them? How did they distribute their wares after they were finished? These, briefly, are the questions I want to try to answer in relation to the metal trades of the eighteenth century, chiefly on the domestic side.

There is a supplementary question arising out of the others. How does it happen that the quality of the work varied so much? Take such a commonplace thing as a gridiron. Why were some of them so elaborately wrought? Some may be ornate in detail and accurately fitted together, while other specimens of like or similar wares are pretentious and unsatisfactory in workmanship, or again simple in form, appropriate to their purpose and admirably

made. How can you account for these differences?

To my mind, nothing calls for more admiration than work exhibiting an economical use of material to produce a given result. The simple is often more artistically true than the elaborate, and the maker of a simple article is often a first-rate workman. Differences in artistic merit, workmanship and style must have been chiefly due to the capacity of the worker, or to natural aptitude. Some were imperfectly trained, or they may have been careless, but others, I feel sure, were hampered by the quality of their materials. A third reason for difference in results would have been in the tools. Some men must have possessed too few for their crafts, and those not always the most suitable for the work they had to perform.

WHERE THE MATERIALS AND TOOLS CAME FROM.

Concerning the materials, you can get a pretty good idea of the position from Yarranton's treatise entitled, "England's Improvement." It is a little earlier than my period, but it is most amusing. Had Yarranton lived in these times he would have been a Tariff Reformer, a whole-hogger. His biting comments on Continental iron shipped to London in competition with native bars from Sussex and the Forest of Dean are thoroughly illuminating, and the reader soon learns that profit before patriotism is not a characteristic peculiar to the twentieth century and a state of war.

The tool problem is, perhaps, the most puzzling of all. The literature on the subject is scrappy, scattered, and rarely contemporary. The examples in our museums are put into cases without any sort of chronological sequence. Nor can you blame the curators of these places for the lack of arrangement. Tools descended from father to son, or passed from employer to journeyman, or from man to apprentice. Most of them were doubtless worn out ultimately and discarded. A few were left in buildings in course of construction, or became hidden in shops where the trades were carried on. They have been found in the demolitions preceding reconstruction; but that fact is more likely to hinder than help those desirous of allocating them to their proper place in the history of manufactured things.

England of the eighteenth century might have been, although it was not quite, independent of outside sources of supply in the metal trades. Iron, copper, tin, and lead were all native materials; brass and pewter she alloyed, the former in Bristol and Birmingham, and to a lesser extent in London. The craft of the pewterer was mainly a London trade, though it was also followed in the provinces. It would not be possible in the time at my disposal to discuss the workshops turning out these metals. In choosing the iron industry for detailed consideration, I have been influenced by my own interest in the ironworks of Kent and Sussex, partly also because I have been able to get some contemporary sketches of this trade with which to illustrate my subject.

HOW THE WORKS WERE ESTABLISHED.

Before the days of steam three things were necessary to the establishment of a successful works: natural power, mechanical means of converting power into work, and air-blast. The situation of an ironworks was determined by the possibility of fixing a water-wheel. The efficiency of the works depended largely on the hammer. The quantity of material produced must always have been roughly proportionate to the number and quality of the bellows.

These were considerations which, more or less modified, must have harassed every eighteenth century manufacturer engaged in winning merchantable metals from native ores. It was not until Watt, Boulton, Cort, and the Darbys came to the front that rapid progress was made. It is curious to notice how the metal trades of our period were hampered because inventions lay undeveloped. Dud Dudley discovered the way to smelt iron with coal about 1619, but it was 1735 before the Darbys began to use coke freely at Coalbrookdale. Even then progress was slow in other places, and as late as 1788 charcoal was the fuel burnt in most of the Sheffield furnaces.

The transition from the tilt hammer to the rolling mill was not so slow, but the old method has lingered right down to the twentieth century. It is quite a mistake to suppose that the steam-engine rapidly replaced the water-wheel. Twenty-two years ago I had a share in demolishing a water-wheel that had supplied power for three generations in an engineering shop employing two hundred men. It drove the foundry blower, all the shafting in the machine shop and sawmill, and a fan for eight forges. The weight of evidence proves that although Boulton and Watt made the manufacturer's decision easier when he had to choose his location, that decision still leaned towards a water site.

How slow the change from wheel to engine really was has been shown recently by Professor

G. J. F. Lloyd in his book on the Sheffield cutlery trade. In 1770 the Rivers Don, Loxley, Rivelin, Sheaf, with some smaller streams in Hallamshire, were turning 133 wheels, and operating between them nearly 900 grindstones, while twenty-eight other wheels were driving as many rolling mills, tilt-hammers and forges. A quarter of a century later there were 118 wheels and five steam-driven works. The higher efficiency of the newer power is shown by the figures. Twelve wheels on the Don then drove 332 grinding troughs, but three of the five steam-plants accounted for 320 stones. Seventy years later, in 1865, there were still thirty-two wheels on the rivers in the district.

The windmill has never competed seriously with the water-wheel as a motor for workshops of the sort we are considering. It was too intermittent to allow of its being utilised for any industry involving the payment of wages week by week. The miller working alone found wind-power as cheap and nearly as serviceable as water. It was no good to an ironmaster whose prosperity depended upon the continuous conversion of ore mined by one gang of men and the equally continuous absorption of the charcoal burned by another gang working elsewhere in the district in which his works were erected.

Of Bellows and Tilt Hammers.

An inquiry into the evolution of the bellows would doubtless yield some valuable information on the steps through which metal-working progressed in the past centuries. In the small, but little-known, museum at the Record Office in Chancery Lane there are two sixteenth-century drawings attributed to Lord Burghley. They illustrate a phase of the lead-smelting industry of Derbyshire. One described in one corner as the "Old Order," shows two men, each standing on a pair of bellows, the nozzles of which are directed towards something meant to represent a furnace. A rough frame is shown behind the men, who were assisted in their labour by two saplings slung in the frame so as to counterbalance the bellows. The other picture, which is inscribed "BurchardesFurnise," is quite an elaborate affair. There is a rough representation of a water-wheel outside the wall, with gear connecting in some way to an overhead shaft of wood in the smelting-house. Four bellows are shown attached by as many connecting rods to the shaft. How the rotary motion of the wheel was to be converted into the reciprocating movement necessary to the working of the bellows, my Lord of Burghley left his millwright to work out in detail.

Mr. Charles Dawson, of Lewes, has kindly lent me a photograph of a clock-face made at Ashburnham, which was the centre of one of the Sussex ironmaking areas. The dial shows in a delightfully quaint fashion some of the phases of the industry: digging the ore, cutting down the trees, charcoal-burning, the interior of the forge, the foundry, and even the check-weighing of the cannon and other output of the works. The picture is the only contemporary representation of a Sussex ironworks of which I have any knowledge.

With regard to tilt hammers, Mr. Lewis, another Sussex antiquarian, suggested in this room some years ago that the original tilt hammer was merely pivoted a little out of the centre. There was a free end opposite the tup on which one or two men stepped to raise it. When they stepped off the blow fell on the metal on the anvil. Afterwards the blow depended upon a cam, or the sprocket of a star wheel on the water-wheel shaft. Sometimes the pressure was exerted on the top of the free end of the hammer beam, at others under the beam between the pivot and the tup. By these primitive means a good merchantable bar of useful length was hammered out of the bloom. It is on record that as early as 1300 the farrones, or ironmongers of London, were agitating against the Sussex ironmasters, who were delivering iron bars so short that their customers' work of making tyres for cart wheels was rendered difficult.

Henry Cort's proposals in 1784 to make iron bars by rolling was only an extension of metal practice. A Major Hanbury who died in 1734 had applied rolling to tinplates, and it is possible that he knew something of the invention of Edmund Henning, who took out Patent No. 262 in October, 1691, to make "iron plates tynned over comonly called tynned plates as good as those brought from and made in Germany." All our current talk about capturing German trade is a very old cry after all!

It was while operating a pair of rolls in an endeavour to elongate a strip of close-plated metal that Bolsover in 1743 conceived the idea of making the silver-on-copper sheets out of which grew the Sheffield plate industry. Rolling for the trade became, as the years went by, an established industry. Bisset's illustrated directory of Birmingham, which was issued in 1800, records several names of firms engaged in it, including that of Matthew Boulton, who

seems to have been a partner in at least half a dozen businesses. In one instance he and another are described as rollers of mixed metals.

The Evolution of the Moulders' Art.

Such, then, were the main equipments of the works from which the craftsmen obtained their materials. The records of the century prove that the little masters were not behind the manufacturers, and that they rose to the possibilities of improving materials, tools and methods. The Sussex moulder who cut a twig from the hedgerow in 1615 in order to ornament his fireback belonged to a race of whom Professor Lethaby wrote that they "knew nothing of art, but wrought it; talked nothing of beauty, but thought it," decorating what they made "with a childlike directness." Quite at the other end of our period I have a slide showing some stove patterns—beautifully carved panels—executed by the Haworth Brothers, who had been students, in Sir Joshua Reynolds' day, at the Royal Academy.

The simple backs of the Sussex "sand-rats" possess a value all their own, but none would wish to reproduce them for use again, whereas the collections of late eighteenth century models in some of our older foundries have been utilised over and over again, and remain as welcome as anything the latest art schools can give us. It is a fine tribute to those artists I have mentioned that their designs are so readily adaptable to modern fireplaces.

Until the foundry business was shifted from the South-Eastern counties of England to the Midlands and Scotland, the casting of iron for domestic purposes seems to have been a singularly restricted trade. Cannon was the chief output, but firebacks and andirons must also have been made by the hundred. The irons served to support the wooden logs on the hearth, while the backs protected the brickwork from the fierce heat of the burning wood, and incidentally served to ornament the centre of many an English home. As soon as the more energetic Midlanders and Scotsmen took up the trade, they branched out in all sorts of ways.

Progress in Kitchen Utensils.

Thus we read that at Carron in 1784 the works were turning out kitchen ranges, which had been invented earlier than that by Bodley, an Exeter man, grates and stoves, kettles, teapots, saucepans and frying-pans, which are described as "neatly and solidly tinned." There is a catalogue of some of these items in the Victoria and Albert Museum, but it is a little later than the eighteenth century, for the water-mark in the paper is 1810. That catalogue comprises a good many additional items such as window fittings, axle pulleys, knockers, and a wider range of pots and pans than the Carron list suggests.

A good deal of information about the development of kitchen utensils can be gathered from patents' specifications. A quite superficial examination of the eighteenth century files has thrown a lot of light on the foundry trade of the period. Among other facts I have discovered that tumbling small castings in a barrel to brighten them is at least 150 years old. In catalogues, old or new, comprising cooking utensils, you always find a drawing and description of a digester. It is one of the oldest iron cooking pots we have, and was the invention of Dr. Denys Papin, a Fellow of the Royal Society. Papin claimed for his pot that "the oldest and hardest cow beef may be made as tender and as savoury as young and choice meat." He did not take out a patent, but issued in 1681 a little book about it, in which he stated that he had "instructed Mr. Mayor, a founder in Old Bedlam, how to make these engines in cast brass, so that anyone may see and buy them of him." Evelyn, under date April 12th, 1682, refers to a meal cooked in a Papin's digester. If we are to believe the diarist, beef and mutton bones were made as "soft as cheese without water or other liquid with less than 8 ozs. of coales."

The transition from copper to iron for kettles had certainly begun in 1754, for in that year W. Johnson applied for a patent relating to their manufacture. He proposed to take "an iron barr and hammer or roll it in a rolling mill to such size or substance as might be necessary for the size of a kettle, boyler or furnace." The sheets thus produced were to be put together with iron forge rivets in the same manner as copper ones. The specification thus enlightens us on several points relating to sheet-metal working, but unhappily leaves us in doubt about the spout. That part of a kettle has always been a hard nut to crack. I recall a conversation with an old ironfounder long since dead. He used to tell with great gusto a story about his grandfather or grand-uncle, I forget which, who could not get his spouts as neat and sound as a rival. He solved the difficulty by disguising himself as a labourer and offering to help a barge-owner to carry pig-iron into the competitor's foundry. History repeats itself, and

since aluminium has come into use, kettle makers have had to tackle the spout problem again, but let us hope in a more neighbourly spirit.

A plain black iron cooking-pot is not entirely nice, and that fact was recognised early in the trade. In 1673 one William Chamberlain took out a patent for a method of "plating tynning of iron, copper and brass." His method appears to have left something to be desired, for more than ninety years afterwards Maurice Clifford applied for a patent to "tin copper which is wrought and pickled and then freezed in the inside on a stake as rough as a coarse file or any other method of freezing which opens the pores of the copper and makes the tinning penetrate." Before the end of the eighteenth century one Hickling had discovered means of coating the inside of culinary utensils with an enamel glaze.

The Art of the Domestic Smith.

Enough of pots and pans; but before dismissing iron some notice must be taken of the domestic smiths. There is possibly no more fascinating craft; it is of great antiquity; it is full of variety, and has always been marked by originality and individuality. Those last-named characteristics had free play in the past, and they will never be entirely eliminated, even in an age when hard work is relegated to the machine-run shop. The man who can take a bit of iron or steel and fashion out of it some useful or ornamental article with a hammer in his hand and the design in his brain is a smith, no matter whether the product of his labour is a simple horseshoe, a highly decorative fitting like a chimney crane, or a tempered instrument. If you will examine carefully the domestic ironwork of the seventeenth and eighteenth century at the Victoria and Albert Museum, you will reach the conclusion that I have reached—namely, that the work is honest hammer and anvil work. Those men used the drill sparingly, relying upon punches for holes, and fullers and sates for fashioning the tenons that fitted them. I am fortunate in being able to illustrate a variety of work that has not hitherto been photographed, while other slides disclose the interiors of several shops in which locks and hinges were made.

A good deal of the individuality that characterises the smith's work must have been due to the way the work was carried out. Until repetition of patterns became general, the builder would finish his share of a job before the smith came on the scene. Then he would make his crane to the chimney, his grille to the finished door-head or his lantern holder to the gateway. Not invariably, but generally, the ironwork would represent the smith's own ideas of fitness, and that, I feel, accounts for much that is fresh, artistic and human in wrought-iron work. Those old smiths had a splendid control over a somewhat hard metal, and they exercised a fine restraint and a commendable economy in the quantity of material they put into a job.

Of the Bell-Founder's Part.

Passing on to copper and its alloys, it is clear that at the beginning of the period brass and bell-metal were used for making cooking utensils for the kitchens of the well-to-do and merchant classes. These were cast in the bell foundries, of which there were a large number in London and the provinces. It seems not unlikely that the decay of bell-founding in the eighteenth century was accelerated by the increasing encroachment of cast-iron cooking utensils. When the orders for skillets and mortars fell off, the bell-founder may have found it hard to keep his works going. Church bells are not wanted every day. In London alone there used to be bell-founders in Shoe Lane, All Hallows in London Wall, Windmill Hill in Clerkenwell, Fleet Street and Whitechapel. There are only two such foundries left. That in Whitechapel has been carried on continuously since 1567. Lester and Pack, who owned it in 1762, cast a bell in that year in the precincts of Westminster Abbey, which fact reminds us that the founding of a bell in a churchyard—sometimes even on the floor of the church beneath the belfry tower—was commonly practised in the country. The method saved a lot of hauling and lifting when the bells came to be hung. On such occasions the people seem to have seized the opportunity of renewing their pots and pans. Thus we read that when a bell was cast at Bridgewater in the thirteenth century 36*s*. 2½*d*. was received for "three leaden vessels with two trivets, one bason with laver, pots and brass that have been sold." In the London Museum, now so worthily housed at Lancaster House, there are two capital mortars which were cast at Whitechapel during our period. As I have hinted, the establishment of iron-foundries in the Midlands, which were managed on factory lines, must have seriously affected the prosperity of the bell-founders. I do not find in Bisset's Directory any evidence that the making of bell-metal cooking-pots was a Birmingham trade in 1800.

While the domestic end of the bell-foundry trade was decaying, there was growing up a remarkable industry in Birmingham, which owed its growth to the increasing wealth of the middle and lower middle classes. With more money to spend there was a surplus after things to eat and wear were provided. Men, and particularly women, I expect, began to look around for more things to use, and naturally furniture began to attract attention. If half the eighteenth-century furniture offered in our curiosity shops is genuine, cabinet-making in those days must have been a prosperous and profitable trade, and its prosperity was reflected in Birmingham.

The Beginnings of Brassfoundry.

The rise of the brassfoundry trade in the Midland city is being investigated at the present time by a committee, whose editor is preparing a history of its rise and developments. Birmingham has been the home of the hardware trade for a very long period. Leland in 1538 wrote in his itinerary that: "There be many smithes in the town that use to make knives and all manner of cutting tools, and many lorimers that make bittes, and a great many naylors."

Half a century later Camden set it down that the town "swarmed with inhabitants, and its streets resounded with the noise of anvils." No reference here to brass, and indeed as late as the Restoration iron was the chief metal wrought in the Birmingham shops, where were "produced instruments of war and husbandry, furniture for the kitchen and tools for the whole system of carpentry." When, however, furniture makers began to weary of wooden latches and handles, and called for something brighter than iron, Birmingham was ready with new ideas.

In competition with Bristol and other centres where brassfounding was already established, Birmingham set out to win a share of the new business, with what permanent success her present position in this department of metal work attests. The instant success of the firms who went into the business is not hard to understand. So much that was required by the new craft was merely modifications of existing trades. The foundry processes were not very different, and the subsequent treatment of the articles must have been familiar to the workmen. Filing, grinding, chasing and burnishing were in the blood of the local workmen, and a new commercial spirit was abroad among their employers. It would have been surprising if the industry had not thriven. How considerable it had become by the end of the century is discoverable from the catalogues at the Victoria and Albert Museum. Twenty-five of them relate to cabinet-brassfoundry, and the variety of articles illustrated is so remarkable that, personally, I have come to the conclusion that all that are represented in the books were not actually made. It appears to be more probable that designs were prepared for trade purposes, and then, if orders came along, the patterns were made and the goods turned out.

An Early Business Combine.

All the same the business attained big proportions, and in 1780 thirty casters of brass in the town were melting down a thousand tons of brass per annum. In that year the actual makers of the alloy advanced the price of ingots, and the casters had to pass on the burden by increasing their prices by 7½ per cent.—a step which was described as a "disagreeable necessity." That was in August, and on October 9th there appeared in *Aris's Gazette*, a local newspaper, "a serious address to the merchants and manufacturers of hardware, and particularly the inhabitants of Birmingham and the adjacent towns." The writer, who signed himself "Bristol," spread himself to an inordinate length, but he made out a serious case against the smelters of copper and the makers of brass. The casters and their wholesale customers learned that "they are imposing on you an enormous advance of more than twenty pounds per ton on copper and upwards of thirteen pounds per ton on brass, without any other reason than that they presume on their power under such association, and that the same must and will be received tamely by you."

The taunt had the desired effect, and "Bristol's" suggestion that a co-operative works for the production of brass should be started was taken up by the victims. A meeting was called in November to discuss the project, and in 1781 the new Brass and Spelter Company was formed with a capital of £20,000. The works, of which I can show you a picture, were off Broad Street, and the thoroughfare to this day is known as Brasshouse Passage. Boulton seems to have taken a keen interest in the preliminary plans, although his other and numerous enterprises precluded his accepting the proffered chairmanship. Unfortunately the shareholders quarrelled with him when the site for the smelter came to be discussed. Boulton favoured Swansea. "If," he wrote, "the works are erected in Birmingham, the work will be

constantly deranged by the interference of a hundred blockheads," and instead of being assisted, will be incommoded by every subscriber that chooses to take an idle walk by ye bank of ye canal." I confess I like Matthew's blunt style, and I am not surprised, when the local majority prevailed, that he resigned. All the same I suspect he left his money in the concern, and became one of its best customers.

Brassfoundry with a Difference.

Side by side with brass-casting there grew up in Birmingham a kindred craft, which was, and still is, described in contradictory terms. Stamped-brassfoundry grew out of the invention of a Londoner named Pickering, a gilt toy maker. He patented in 1769 "a new method of performing that kind of work called chasing, for gold, silver, brass, tin and other metals, but more especially to be used in the production of coffin furniture, also ornaments for coaches, chariots, cabinet brass work and domestic furniture." Pickering claimed that his method was more expeditious than anything then practised, and that it was "far superior in beauty and elegance to anything of the kind (not being actual chasing) ever yet performed."

It is quite clear from this that the cost of chasing was the bugbear of the finishing departments, and the circumstance confirms my own view that a good deal of the metal turned out in the foundries was sold "out of the sand." You cannot explain such prices as 7*s.* 6*d.* for an elaborate cast-brass clock in any other way. There is evidence that these articles were sent to France, and my own opinion is that they were chased and lacquered by French workmen for the French markets.

About this time a Birmingham brass and copper worker adapted stamping to more utilitarian wares—to warming-pans, to scale-making, and to frying-pans. A few years later John Marston, a brass-caster in the town, and Samuel Bellamy, a die-sinker, devised means for piercing brass, and employed coloured foils behind the perforations to enhance the appearance of their wares. There are some admirable examples of this sort of work represented in a catalogue marked "R. & Co.," and published probably about 1780. The handles, cloak-pins and escutcheons shown are described as "japanned middles set in gold coloured rims, with mahogany moco, tortoise and green grounds." I confess I do not know what a moco ground was like, but it sounds rich. Other decorative features included enamelled centres, of which there are examples at Brighton, and not long ago I came across a piece of furniture in the Leicester Museum mounted with this type of handle, though one is inclined to question the accuracy of the official description, which ran, "handles decorated with Battersea enamels."

As the stamped-brassfoundry trade grew, comparatively large pieces such as picture and mirror frames came to be made of sheet-brass. I have not had an opportunity of examining an authentic example, but I cannot think they were made in one piece or at one operation. The pattern always repeats, according to the books, and I expect the metal was stamped and shifted for its whole length. Any little irregularities arising from this way of working could be made good with a hammer and punches, and the frames would be mitred together, sweated or brazed and then polished, water-gilded and lacquered. There are two other brass departments represented by the catalogues—cock founding for brewers and plumbers, and fittings for lighting. The former seems to have been begun in Birmingham about 1770, but the catalogue is of later date, and the gas-fitting trade did not begin before 1812, in which year Murdock discovered how to make coal-gas.

Tin Wares for the Poorer Folk.

Brass and copper wares, however, were still beyond the purchasing power of the common people, who were the chief customers of the tinplate workers. All through the century it was a pretty well organised industry, and the interests of those connected with it were well served by the Worshipful Company of Tinplate Workers, *alias* Wireworkers. Their charter was granted in 1670, on the petition of the men engaged in the trade, and the records show that a hundred of the journeymen paid a subscription to the funds raised to secure incorporation. Southwark was the centre of the trade, in which were men who were by no means backward in asserting their rights. They prosecuted pedlars who hawked inferior wares from door to door, they discharged their own officials on proof of their neglect of duty, and fined shifty members of the company who were caught making goods of "damaged stuff and materials." Their authority extended beyond London, as far indeed as Woolwich, Northampton and Worcester. An interesting bit of special work was the periodical publication of a piecework book, affording the basis upon which wages were paid to workmen. The first was issued in

1695, and the list has been revised seven or eight times, the last occasion in 1900. The list of contents in the fifth edition of 1761 contained the names of many articles no longer used, or if used, no longer made in tinplate. It is rather to be regretted that there is no catalogue of domestic tinware at South Kensington. Possibly the trade was purely English, and without a foreign trade there may have been neither need nor inducement for catalogues.

Pewter as a Domestic Metal.

Until the fifth decade of the eighteenth century the metal commonly used for the table appointments of the middle class was pewter, and a garnish of pewter was to be found in most houses, and also in the mansions of the well-to-do, who would use the ware for everyday use and in the servants' hall. Comparatively little has come down to us, and I explain that fact on two grounds. The metal is soft, and consequently as soon as it went out of daily use and was no longer subject to continuous care, it would become shapeless and dirty. The other reason lay in the ease with which pewter could be remelted. The commonest articles, plates and dishes, were made by pouring the metal into iron moulds, and there would be no inducement to harbour bent, cracked and worn-out utensils. The lumber-room has saved a great deal from destructon, but why put old plates in the attic when the itinerant pewterer was prepared to melt them down on the kitchen fire and leave you as many, or nearly as many, new ones at the cost of a few shillings? I do not suggest that that was universally done; probably most of the old metal went back to the shopkeeping pewterers, who made an allowance for it consistent with the price of tin and the value of the order for new wares. One meets this "contra" system at all sorts of turns, and it is pretty certain it was customary in all trades. There is only one reference to pewter in the Victoria and Albert Museum catalogues, and that is in the nature of an interpolation. In the ironfounders' catalogue to which I have referred there is a sheet of MS. on which there is a note that "the price of pewter plates and dishes fluctuates sometimes four times per annum, and sometimes more frequently." As there are neither particulars nor prices of pewter wares in the catalogue, the presence of the sheet is explained by assuming that the founder factored the goods—that is to say, he bought them for resale, sending consignments with his own wares r his customers required.

The Invention of Sheffield Plate.

In 1743, however, a new industry was begun in Sheffield, which was to compete with silver in beauty and attractiveness, and in price with pewter. The wares that the new craftsmen began to produce were known as Sheffield plate; they are now universally described as "Old Sheffield Plate." The Victoria and Albert Museum is fortunate in possessing half a dozen catalogues devoted to this branch of the metal trades. From fragmentary evidence carefully collated, Mr. Bradbury has been able to prove that the volume of business in these wares at home and abroad assumed remarkable proportions, and four of the catalogues bear marks which show that they were used for trade with the Continent.

Most Sheffield plate is what is technically called hollow-ware, and is made from a sheet of metal, silver on one side and copper on the other, or silver on both sides with copper between the two. It was the invention in 1742 or thereabouts of Thomas Bolsover, a Sheffield cutler, who hit upon the method, after passing a piece of close-plated strip through the rolls. His material was a little too short for his job, and when he found the rolls elongated it without separating the constituent parts, he thought the matter out and began to experiment. His process is now known as plating by fusion. The first step was to prepare a copper slab or ingot containing a little zinc and lead. A commonly used size was 8½ ins. by 2½ ins. by 1½ ins., the last dimension being the thickness. The top surface, or both top and bottom, if two silver faces were required, was filed flat and scraped smooth. Then a strip of silver slightly alloyed with copper, or two in some cases, was made ready in the same way, and the two or three pieces were superimposed with the prepared faces in contact. The outside silver surfaces were then covered with other strips of copper or iron coated on the contact sides with whiting. The three, or five, pieces were then wired together and the joints painted with a borax flux. As soon as the last-named was dry the block was ready for the furnace. This was heated with a clean coke or charcoal. As soon as the observer saw the silver begin to "weep," that is to melt at the edges, he withdrew the block from the furnace with tongs which seized the sides. When the block was cool, the wire was removed and the copper plates taken off. The ingot was now ready for the rolls, in which it was reduced to the usual gauges for making hollow-ware, candlesticks and fancy articles.

The quality of the resulting product was, of course, proportionate to the original thickness of the plate or plates of silver, which varied from as little as $\frac{1}{16}$ in. to as much as half an inch. The material lent itself to die and press-work, to repoussé, and to piercing. Bolsover did not at first grasp the possibilities of his own invention. His own trade lay chiefly in small articles, buttons, buckles, and patch and snuff-boxes. A cutler by trade, he seems to have cultivated that side of his business. His apprentice, however, one Joseph Hancock, developed the new industry, and became in time a roller of silver-faced copper to the trade, dropping the manufacture of finished articles as his business grew. Sheffield was the home of the trade, but London and Birmingham entered the field later in the century, and Matthew Boulton was one of the men to engage in it. Bolsover was neither the first nor the last to experiment in plating. The files of the Patent Office include references to Horsley's method in 1783, which consisted in filling plates or leaves of metal with lead or a hard alloy of tin and spelter, while in 1779 one William Bell invented a process for making buttons and buckle shells, by passing sheet metal through rollers, one of which was engraved like a sunk die, while the other had the corresponding embossed design on it. In 1790 John Whitworth sought protection for his method of reinforcing a silver-lined mould with a resin-faced tinplate backing which was pressed into it.

Toys and Toy Shops.

These references to fancy wares and their manufacture bring me to a curious branch of the retail trade known as "toys." The term has nothing to do with playthings, but is applied to those little articles which add so much to the amenities of social life. Nowadays it is practically always qualified by the word "steel." Steel toys include corkscrews, keyrings, button-hooks, nutcrackers, and the like. They usually constitute part of the stock-in-trade of the cutler, the tool dealer and the ironmonger; but the lady of fashion and her male companion in the eighteenth century went to the toy shop for many odds and ends. We may turn to three contemporary sources for enlightenment about these places of business. In the early part of the century the advertising columns of the *Spectator* afford plenty of references to the toy-shops in London. All sorts of things were mixed up with the regular wares, and I expect the proprietors of these specialities paid for the advertisements through the occupier of the shop where their goods were exhibited and sold.

Here are a few examples of what were offered: At Mr. Markham's, at the "Seven Stars," under St. Dunstan's Church, and at Allcroft's in Cornhill, a quack medicine, which would cure anything, from apoplexy to infant fits, was sold side by side with toys. Mr. John Hannam, who kept a similar shop at the sign of the "Three Angels, near Foster Lane in Cheapside," sold a Spanish blacking for gentlemen's shoes. A few months later, in 1711, he advertised a mouth-wash and "incomparable perfuming drops." Two years afterwards there were four angels presiding in or near Foster Lane, for the business was then owned by Mrs. Hannam, who was pushing a hairwash. Another toy-shop, opposite Garraway's Coffee House in Exchange Alley, was kept by a Mr. Penkethman, who took subscriptions for engravings. More to the point is a later advertisement of Allcroft's, who styled his shop "The Blue Coat Boy." He offered "Venetian straps neatly fixed on boards" for polishing razors, penknives and lancets. It is significant that this article, which was sold for a shilling, was also offered by a Mr. Cooper, whose toy-shop was at the corner of Charles Street in the Strand. It seems pretty certain that the toy-shop was a centre of daily gossip, and that the "Jew" in the West had no dealings with the "Samaritan" in the City. Thus the novelties had to be offered East and West of Temple Bar.

Side Lights on Toy-making and Selling.

At the other end of the century there was Bisset's Directory, to which I have already referred; but of 335 entries in the index twenty-four relate to toy-makers whose wares are described as steel, brass, wood, glass or ivory. The term had a wide significance and covered pencil cases, watch chains, buckles, snuff-boxes, buttons and snuffers, besides some of the articles already enumerated. Bisset claimed that Birmingham possessed the toy-shops of the world, wherein—

> "Inventions curious, various kinds of toys
> Then occupied the time of men and boys."

I ought to have explained that this directory is introduced by a rhyming itinerary of the city. It throws a curious sidelight on child-labour, for a few lines further on we read that—

> "Blooming girls at work were often seen
> That twice their ages joined were scarce fifteen."

By way of extenuating this exploitation of children, Bisset praises the "salutary establish-

ment of the Sunday-school," where the unhappy youngsters, after working all the week, were taught to read and write and "every attention is paid to their morals."

The third contemporary account of a toy-shop is in R. Dodsley's play of that title. The master is represented as "a general satirist, yet not rude or ill-natured; he will strike a lesson or illustration out of a snuff-box, a thimble or a cockleshell." The description of the shop is amusing and lively. The proprietor advanced money on watches and jewelry, and had a word for all who came to his counter. The customers represented include a woman wanting a mirror, another asking for a little box, a bevy of ladies in search of a stuffed dog, and a gentleman needing an ivory pocket-book. Another dandy is hypercritical about the adornment of snuff-boxes, and is severely handled by the toyman; but a young man who asks for a plain gold ring and denies that it is for his bride, withdraws the lie when the old man gives him a little fatherly advice. A woman buys a mask, and an old man tries spectacles with tortoiseshell and silver rims. There is not much hardware here, nor much metal, but it is clear the stock was remarkably varied. Just by way of comparison I took a turn, while I was writing this paper, in Cheapside, where there is just such another shop, and if I had dared venture in without making a purchase, possibly I might have encountered a similar philosopher amid quite as mixed an assortment of wares. Anyway, over two centuries the toy-shop keeper has always been the snapper-up of unconsidered trifles, the Autolycus, in short, of the retail trades.

Beautifying a London House.

The overlapping which this inquiry into the toy-shop business has disclosed was not peculiar to the distributing trades. Some years ago I had an opportunity of abstracting some entries from the domestic accounts of a family residing in Dover Street, Piccadilly, with a country house at Gosfield. The period covered extended from 1726 to 1736, during which time the house in Dover Street was "repaired and beautified at a charge of £850." The Hon. Mrs. Knight was a shrewd businesslike woman, who chose her tradesmen with a nice appreciation of values. Her first ironmongers were William and Charles Sparke, whose address, unfortunately, is not furnished. There were charges for such items as a fish-spit, larding pins, copper pudding boilers and patty pans, basting ladles, bread graters, beer pots, and picture hooks. Furnishings for the fireplace include a "copper scuttle, 21*s.*; one pair of steel tongues, 25*s.*; and one pair bow-spring tongues with stay, 2*s.*" You will recognise the last description as referring to those handy little instruments which are always open, but cannot spread too wide for a hand's grip, because of the pin from one member through the other.

Mrs. Knight was a patron of her sex in business. There were frequent entries relating to the bills of one Lucy Bayles, who owned a furnishing establishment. There was an account for £116 in 1731, which was largely accounted for by an entry for "Three very fine mahogany bookcases with large glass dores, ye mouldings carved, good locks and brasswork, £81." Apparently the lady furnisher did not stock cabinet brass-foundry, because elsewhere her accounts read: "Paid for locks, hinges and brass buttons 5*s.* 8*d.*" Mrs. Lucy Bayles's handyman was one "hary," who, judging from the jobs he took in hand, must have been a good all-round workman, and withal an ill-paid one. There could not have been much for the man when the mistress was satisfied with 2*s.* 4*d.* for eight hours' work and 3*s.* 4*d.* for a whole day's jobbing at Mrs. Knight's house. Mistress Bayles had no more scruples about trespassing on other people's preserves than the toy-shop owners. She competed, for instance, with the apothecary when she charged her customer half-a-crown for half-a-pint of Daffy's Elixir.

Other little glimpses into shopkeeping in the first half of the century occur in these accounts. There was a Mr. John Browne, a silversmith, but not above doing repairs to anything that was brought to him. A coffee-pot, entered as 30 ozs. 5 dwts. at 7*s.* 6*d.*, £11 6*s.* 10*d.*, must have been silver, but a "tea-kettle lamp and stand, polished, 5*s.* 6*d.*," would have been of a baser metal. Browne undertook cutlery repairs and charged 3*s.* 6*d.* for two penknife blades and sixpence for "two pairs of sisers ground," and a shilling for setting two razors. The toy-shop element occurs with such items as blacklead pencils, which cost twopence apiece, a pocket-book priced at 17*s.*, pens, ink and paper, a travelling trunk, china cups, a flint bottle and brushes.

When repairs were required in what are now called, by the estate agents, the offices they were entrusted to another class of tradesman. A Mr. Philip Spood was paid 4*s.* for cleaning and mending "Ye jack and new centering ye worm and oylying ye wheels and pulleys." The same man had 2*s.* 6*d.* for some repairs to

the casements, 8*d*. for putting a foot on the tea-kettle trivet, and 6*s*. 6*d*. for a new strong-box to hold "ye flambeaus," while for "facing two cast smoothing irons and a wrought smoothing iron 4*s*. 6*d*."

Spood was evidently a jobbing workman, because he was not ordered to supply the new jack when Dover Street was beautified. In a long account, chiefly for carpets, curtains, and fabrics, one John Cox—a sort of Maple, I take it—included £6 3*s*. for "one large jack with a multiplying wheel, pulleys, line, and two chains"; but it seems clear Mr. Cox did not fix it, for an earlier item in the account runs, "paid a smith to take down and clean a large jack, 10*s*."

Defoe on Distributors.

One other glimpse of these methods of distributing wares made in London and other centres is afforded by Defoe in his account of a tour through East Anglia. The author of "Robinson Crusoe" mentions a fair at Bury St. Edmunds in 1722 "for diversion more than for trade," a "fair for toys and trinkets," but when he came to Cambridge he wrote of Cheapside and several other streets in Stourbridge Fair which was "kept in a large cornfield near Casterton, extending from the side of the River Cam towards the road for about half-a-mile." The space is still unbuilt upon. Cheapside is no longer the chief street in what remains of the fair, where the only street that has kept its name is Oyster House Row. One evening in June this year I came up the road from the River Cam and tried to visualise the scene, but the glory of the Fair, which old Cambridge pronounces "Sturbidge," has departed. The cornfield is now a dreary waste and no longer the venue of "all sorts of trades, who sell by retail and who come from London with their goods . . . toy-shops, braziers, turners, and pewterers." I have omitted some, but you may take Defoe's word for it that there were present "all trades that can be named in London."

DISCUSSION.

The Chairman (Professor William Gowland, F.R.S., F.I.C., F.S.A.), in opening the discussion, said that, as described by Mr. Young, and as was well known to most of the audience, the conditions under which metalworkers of the eighteenth century carried on their work differed greatly from those which prevailed at the present time. Rolling mills and steam-hammers had not displaced the tilt hammer and the water-wheel. Again, there were no machine tools or self-cutting lathes, or automatic tools of any description. So that there was the disadvantage that the output of a given workshop was only very limited. But, on the other hand, the conditions were not always disadvantageous, because they led to a development of special skill and ingenuity in the individual worker which was not always found at the present day. With regard to water-wheels and tilt hammers, they had had their day; they had been long on their death-beds, but they were by no means yet dead. About seven years ago he visited Vulpmes, a very famous old iron centre near Innsbruck, and there he found in every forge—and there were a great many, not less than forty or fifty in the town—the water-mill and the tilt hammer still in very vigorous and satisfactory work. One curious thing about the work was that in the old days Vulpmes was a famous iron-smelting centre, but that had been given up because they found it was cheaper to buy Bessemer steel from a new works which had been erected a short time before in Styria. So there were these very old appliances, working into sickles and into plates and sheets and the like, one of the latest forms of the metal iron. As was well known, in forging a piece of metal it was necessary that the blows should not all be delivered with the same rapidity. At certain stages of the operation the blows had to be slow and at others quick. That was effected at Vulpmes in a very simple and ingenious way. The man who was doing the forging sat in front of the hammer, and with one hand he manipulated the forging and in the other he held a cord, which was connected with the sluice of the water-wheel. When the man wished the blows to be quick, he opened the sluice, the water-wheel revolved at a greater rate, and so he was able to regulate his work quite as satisfactorily and perfectly as could be done with any modern mechanical appliance. With regard to the materials which were used by the metalworkers of the eighteenth century, he thought it was acknowledged generally that the wrought-iron work of that century exhibited a marked decadence compared with that of the previous centuries, and he thought it was also generally admitted that unfortunately from about the fifteenth century the English smith seemed gradually to have lost the foremost place which he had previously occupied. In cast-iron there were few examples of note in the eighteenth century. The fire-backs of the Sussex and other foundries had been given up owing to the introduction of the hob-grate. Then the founders did not seem to have turned their attention, except but rarely, to anything but the making of ordinary castings—kettles, pots, and the like. Yet in Japan in the eighteenth century there was a vast array of articles of domestic ironwork which were ornamented not only by designs in relief but also inlaid with other metals, and it seemed very curious that in Japan and in this country during that same century there should be such a different class of cast-iron work. The cast-iron work in Japan, more particularly the relief work, was extremely sharp in detail of design owing to all the castings

having been made by the *cire perdu* process, and by using a fusible metal and pouring it into moulds which had previously been heated almost to redness. About the middle of the eighteenth century there was a very important invention made by Réaumur. When a casting was taken from a mould the surface was hard and brittle, and could not be chased or easily worked with any tool. By Réaumur's invention of malleable cast-iron, which he obtained by embedding castings in ferric oxide and exposing them to a considerable heat for a definite period of time, the surface of the metal became soft and available for any decorative work that could be put on it with a chaser, or by inlaying. Yet the English founders, till long after that invention was made, did not seem to have taken advantage of it, and when they did they only made use of it for the production of castings which were to be used in place of more expensive forgings. There was one point with regard to Japanese ironwork which he would like to bring to the notice of the audience, and that was that a Japanese iron article was never polished with sand-paper, or with polishing materials such as were used in this country. During the operations of making it, it was coated with a rich brown permanent rust, so that the object only required to be rubbed from time to time with a silk or a woollen cloth. That rusting was performed in a very simple manner. The article, a kettle for instance, was heated over a brasier, and when it had reached the proper temperature it was then rubbed with a liquid consisting of plum vinegar with iron in solution and containing iron oxide in suspension; and the rubbing was continued until the required depth of the incrustation of rust had been attained. With regard to pewter, pewter of the eighteenth century consisted usually of an alloy of lead and tin, but sometimes of tin to which a small quantity of copper had been added. That alloy pewter, especially the tin-lead alloy, was of very ancient origin. It was in extensive use by the Romans during their occupation of this country, and many examples of it had been dug up on the sites of Roman cities. Many of those he had analysed, and several he had found to have precisely the same composition as the best English pewter; that was, 80 parts of tin and 20 of lead, so that it would be seen that pewter was in use very early in our era. Our pewter, as he had said, consisted of 80 parts of tin and 20 of lead, but just after the end of the eighteenth century there was a very elaborate investigation undertaken by the French Government, and the result was that it was found and really definitely determined that 18 per cent. of lead should be the maximum which should be permitted in all pewter which was intended for the manufacture of vessels for domestic use, in order that liquids which were kept in those vessels should not become contaminated with lead and hence be poisonous. Of course, it was just possible that in France, where sour wines were kept in pewter, it was necessary to have that low percentage of lead, but he had not met with any case of poisoning from liquids which had been kept in our own pewter. There was a very interesting explanation why pewter should be poisonous, which he had found in an old Chinese book on metallurgy. The author said: "It is well known that arsenic under the influence of the feminine principle of Nature in the lapse of ages becomes converted into tin. Hence the pewter which was used in the manufacture of those vessels which were poisonous had consisted partly of arsenic and partly of tin, sufficient time not having elapsed for the conversion of the former into the latter metal." With regard to brass, brass was an alloy of copper and zinc, and brass we owed to the Romans, who made it during the reign of Augustus just at the beginning of our era. Zinc as a distinct metal was not known then; in fact, zinc as a distinct metal was not known in Europe until the sixteenth century, and was never used, even experimentally, in the manufacture of brass until about the beginning of the nineteenth. The Romans discovered that by melting copper with a certain ore—that was calamine—that a golden-yellow alloy brass was obtained. So effective was that method that it survived long after Roman times, and in fact until about 100 years ago it was the only method by which brass was made in Europe. With regard to bells, he was very interested to hear that in England bells were cast in the churchyard or in the neighbourhood of a church. That had been the practice from probably about the tenth or eleventh century in Japan, and there it was almost necessary, because those old bells of Japan weighed from forty to fifty-six tons.

Mr. John Slater, F.R.I.B.A., said the direction which the paper had taken was not quite what he had expected from the title. He thought the author was going to refer more to the eighteenth-century metalwork in railings and grilles, and that sort of thing. He was quite sure everyone present must have been extremely pleased to see a picture on the screen of the beautiful iron railing outside the house in Great Ormond Street. London and Liverpool were very rich in railings of that sort.

Sir Henry Trueman Wood said, as one who had made a study of the history of inventions, especially those of the eighteenth century, he desired to bear testimony to the extreme interest of the paper. It might sound a little conceited for him to say so, but he had found in the lecture a good deal which was new to him, and had found practically nothing which required correction. In considering the places where iron was made, it must be remembered that not only a source of power was required, but also a source of fuel. There was not much doubt that cutlery was first made in Sheffield not only because of the water power available, but on account of the forests which used to be

there, although they had disappeared before the eighteenth century. With regard to the picture thrown on the screen of the way in which the bellows worked, that was an artist's picture of a mechanical invention, and an artist's picture of any mechanical work was always below contempt; it might be beautiful but it was never accurate. The shaft evidently worked the pistons or rods which actuated the bellows by a series of tappets, which forced down the bellows and drove the air out, but there was nothing to indicate how the bellows were raised. With regard to the other picture in which the rod working the bellows was actuated by a cam, and which the author did not seem to appreciate, it was simply that the artist did not know what a cam was; he had made it circular, and a concentric circular cam would have no effect at all. It might be interesting if he mentioned that when the steam-engine was first used to drive bellows, the way it was operated was that it was set to pump water up. The water was then used to drive a water-wheel, and the motion was communicated from the water-wheel by suitable gearing of some sort to the bellows. That seemed rather curious, because a reciprocating motion was first turned into a circular one, and then turned back into a reciprocating motion again. When real blowing engines were first made, he thought they were worked direct from the pistons of the steam-engines. Reference had been made in the paper to Yarranton, a most remarkable engineer, projector, and author. He was really the first man who had made good tin plate in England by going over to Germany and finding out how the Germans made their plate by rolling. The old tin plate in England had been made by hammering, by which method as good plates could not be obtained as by the rolling method. Yarranton did not profit much by his invention, because somebody else slipped in and obtained a patent. With regard to bells, what the Chairman had said was very interesting, because it showed that where the same conditions existed the same means had to be adopted of meeting them. It was not only in Japan that bells could not be carried about; in England, before the days of railways and canals, they could not be transported from one place to another, and they had to be made where they were going to be rung. He fancied that the London bell-founders had for the most part only small workshops where they cast small wares, and if they got an order for a bell at Canterbury or some other place, they went and cast it in the churchyard. He believed all the big bells in England had been cast in that way. With regard to water-mills, he thought some water-mills could be found in England at the present time which were doing useful work. He knew that the last weaving cloth mill of Bradford, which had been given up only a very few years ago, had had a water-wheel, which had originally been the reason for the establishment of the mill there, and it was at work not many years ago. He had tried to find out the origin of windmills, and he had utterly failed. It was certain the Romans used water-mills, and he remembered some reference in a Latin author to mills, which, like the water-wheel, were driven by wind; so they were pretty old.

The Author, in reply, said with regard to Mr. John Slater's remarks, Mr. J. Starkie Gardner had already given a lecture on ironwork before the Society, and he (the author) would have been trespassing upon that gentleman's ground if he had talked upon things about which he did not know so much instead of the particular side of the matter which he had discussed that evening, about which he had some knowledge. With regard to Roebuck's invention of the engine for blowing, he once had access to some of the Carron papers, and among other things he found was a reference to the pumping of the air into a big cylinder or chamber; it was most vague, and one could not follow it, but among the other sketches which he had of Krupp's works there was a very crude and rough drawing made by Alfred Krupp himself, about 1835, showing bellows and a number of other details, and there was certainly a representation of a pair of big bellows delivering air into some sort of cylinder, from which apparently the air was subsequently drawn for use in the furnace.

On the motion of the Chairman a vote of thanks was accorded to Mr. Young, and the meeting terminated.

BRITISH DYE INDUSTRY.

The Government's scheme for the creation of an aniline dye industry in this country was explained by Lord Moulton to a large gathering of business men from Lancashire, Yorkshire, and adjoining counties in the Manchester Town Hall on December 8th. The Lord Mayor of Manchester, Alderman McCabe, presided.

Lord Moulton said he was not present as a representative of the Government or an advocate of any particular scheme. He was there as one giving advice. When he began to investigate the question he found that England consumed some £2,000,000 worth of dyes, which were essential to industrial products valued at something like £200,000,000 a year, on which at least one and a half million men were dependent. Of dyes of that value barely one-tenth was produced in this country, and stocks were rapidly diminishing. There was only one nation—the Swiss—from whom help could be expected, and he knew that pressure of the most intense kind would be put upon them by Germany to prevent them from giving that help. Firms in this country were manufacturing successfully in spite of German competition, but they could only give a quite inadequate supply.

That was the immediate future. But supposing the war was finished and we emerged politically

free, what position should we step into industrially? The textile industries would step into a slavery to the Germans as absolute as they hoped to put us in in a political and military sense. They would be over-charged for dyes and hampered until the Germans had the capital and works to challenge their very existence. Among the chief causes of the position of this country was the English dislike to study—the failure to prepare intellectually for the task that had to be undertaken. The English, he believed, could do the work as well as the Germans, and in their great works they would find English chemists as efficient as the Germans. Unfortunately the holders of capital in this country had little sympathy with knowledge which they did not themselves possess, and there was no career for the young man who wanted to study. In no other respect was this nation at a disadvantage as compared with Germany. The whole of these dyes could be manufactured in England, if the proper plant were put up and the proper men chosen to guide it, with as great a certainty as a casting was manufactured. There must be a great national effort to create a company, for whose success three conditions would be necessary. It must be large, its loyalty must be beyond doubt, and it must be co-operative, the producer being the consumer and the textile trade, the dyeing trades, and the pigment trades working together to secure these conditions. The company must be under national control.

A resolution approving a national effort was carried unanimously.

PANAMA CANAL TRAFFIC.

The *Canal Record* publishes a review of the traffic carried through the Canal during the first two months since it was opened, August 15th to October 15th. In this period the commercial vessels which have been using it have carried through 583,949 tons of cargo. The traffic has followed fairly well-defined trade routes, and the course of the great majority of vessels may be roughly classed in four great groups.

The heaviest traffic has been between the Atlantic and Pacific coasts of the United States. Manufactured goods of great variety and general merchandise are carried from the Atlantic seaboard, principally from New York, and secondarily from Boston, Philadelphia, and New Orleans, to the principal California and Puget Sound ports; also to Honolulu. On the eastbound voyage these vessels carry chiefly canned fruits, vegetables, and salmon, lumber, grain, sugar, pineapples, and wine. This trade is restricted to vessels of American registry, and nearly all the American vessels which have used the Canal have been engaged in it. During the period of Canal operation 24 vessels have passed through eastbound on this route with 151,290 tons, and 25 westbound with 135,214 tons. These passages, 49 in all, have constituted approximately 44 per cent. of all the 113 passages through the Canal. The total cargo carried on this route, 286,504 tons, has been almost exactly 50 per cent. of all cargo.

A route between the eastern coast of the United States and the west coast of South America has been second in cargo through the Canal. Northbound vessels carry principally nitrates from the fields of Chile, with secondary cargo of raw material products of the western countries of South America, and southbound vessels carry manufactured goods from the United States and Europe. The northbound traffic, passing thirteen vessels with 93,189 tons, through the Canal during the two-month period has considerably exceeded the southbound consisting of three vessels with 18,000 tons and one in ballast.

There has been a marked, though probably seasonal, traffic from the Pacific ports of the United States and southwest Canada to Europe with grain. Ten vessels, each heavily laden, have gone through eastbound, with 71,560 tons, and eight vessels, all of foreign registry, have gone from the Atlantic to the Pacific in ballast, to return on this route with grain. In addition, one vessel, which went through the Canal with 6,000 tons of manufactured goods from Antwerp to Tacoma, is to return with grain.

The fourth great route has been from the Atlantic seaboard of the United States to China and Japan with refined petroleum in bulk and in cases and other petroleum products. Four vessels have gone through in this trade from the Gulf of Mexico with 24,931 tons, and four from Philadelphia and New York with 26,570 tons, an aggregate of 51,501 tons. No vessels have gone in the other direction on this route.

Next to the four principal routes just described, the most notable development has been the coal traffic from the middle Atlantic seaboard of the United States to the Pacific coast of North and South America. Five vessels, four from Norfolk, with 22,535 tons, and one from Baltimore, with 6,000 tons, have carried coal to the upper Pacific, and one vessel from Baltimore has carried 6,010 tons to Valparaiso. The total coal carried has been 34,545 tons. None of these vessels have returned through the Canal to this time, but it is understood they will load with Pacific coast products for the eastern United States and for Europe.

The development of a line from Liverpool around South America, with vessels sailing both ways *viâ* the Canal, has been arrested by the European war. The only vessel which used the Canal in this route was the steamship *Potosi*, which passed through the Canal on September 25th, on its way south, along the west coast of South America. It was held in the bay at Balboa, awaiting orders, but sailed on October 14th.

The military service of the United States has used the Canal for the passage of one Army transport and one Navy collier, both from Pacific to Atlantic.

ENGINEERING NOTES.

Latest Developments in Submarine Signalling.—Water has many advantages over air for the purpose of submarine signalling. There is less absorption in water, and consequently the signal is not only more reliable, but is transmitted to a distance many times greater than when it is transmitted through air. The sound is not carried away in stormy weather, neither is it affected by atmospheric conditions, as is the case with wireless telegraphy. Further, submarine signalling permits of accurate determination of the direction from which the sound is proceeding. The first method employed for producing the sound was through the striking of a bell, and the signals were received by means of a microphone attached to the skin of the ship. The signalling bell on lightships is actuated by compressed air stored in a reservoir. The actuating wheel has projections on which, as the wheel revolves, a number of strokes follow each other, the different intervals being peculiar to certain signal stations, so that the captain of a ship, by counting the strokes of the bell, can determine which lightship he is approaching. In order to cut out water noises and other noises on board ship due to the machinery, it has been found necessary to suspend the receiving microphone in a tank of water. One of these is attached to each side of the bow inside the ship. From each tank wires are run to a change-over switch and telephone receiver. With this arrangement first the starboard and then the port microphone can be connected to the receiver. The captain has only to turn his ship until the sound is heard with equal intensity on each side, to know that the ship is then pointing in the direction from which the sound is coming, and in this way he can take compass bearings of the lightship on which the bell is situated. Less sensational than wireless telegraphy, it may be questioned whether its actual practical utility to the merchant marine has not been greater. A new form of transmitter, which has been finally developed by Professor Fessenden in the United States, is termed an oscillator, and represents an important step forward in the science of navigation. With the object of producing very powerful blows on a diaphragm in very rapid succession, a copper cylinder is caused to vibrate along its own axis by means of a powerful high-frequency alternating current (500 periods per second) in the following manner. The copper cylinder is surrounded by a coil in such a way that the latter forms the primary and the copper tube the secondary of a transformer. When high-frequency alternating currents are passed through, the primary corresponding currents are induced in the copper cylinder, which floats in the air gap of a very powerful magnetic field produced by an electro-magnet. The effect of the alternating currents and the constant magnetic field is to make the copper tube vibrate violently and strike the diaphragm. Telegraphing is accomplished by means of making and breaking the supply of alternating current with an ordinary telegraph key. It is usual to use a submerged microphone and telephone receiver for receiving the signals, but the transmitter or oscillator described above is capable of reversing its function, and can be used as a receiver by connecting a telephone to the primary winding. This type of transmitter was first tested by suspending it in 12 feet of water at the Boston Lightship, and signals were heard with a microphone lowered from a tug 31 miles away. The system has been tried in submarine boats, and proved itself of immense value, demonstrating that a flotilla of submarines so equipped would be able to make a combined attack on an enemy, only one needing to show its periscope in order to direct the others. When the apparatus is used as a telephone, conversation can be carried on at 400 to 500 yards. Captains of vessels could thus talk directly to each other without the medium of a telegraph operator. Among the important uses of this method of submarine signalling are the taking of soundings and the detection of icebergs by means of the echo. Sound travels in water at the rate of 400 feet per second, and instruments have been devised for recording the time taken for the echo of the signal to return after being reflected back from the bottom of the sea, and thus the depth of water can be ascertained. Similarly, signals are reflected back from icebergs, and their presence and direction ascertained on board a ship whilst going at full speed.

Water Power from an Artesian Well.—The utilisation of water power is common in Switzerland and other mountainous countries, where large hydro-electric power-stations have been working for some years. We hear, through the *Electrical Review*, of a unique case at Thayo-mindah, in Queensland, where water power is derived from an artesian bore well and used for generating electricity for the district. The water pressure from the well when shut down is said to be 270 lbs. per square inch, and 190 lbs. when the jet is playing on the Loffel water-wheel. The power which can be thus produced amounts to 27 horse-power. There are twenty-five consumers, and the price charged for lighting is one shilling per week for each lamp. The lamps are 50 candle-power, and as there is no other electric or gas supply in the neighbourhood the tariff may be said to be very reasonable and simple.

The Battleship versus the Submarine.—Armour has made a successful defence against the gun, and the gun is effective against a torpedo attack when delivered by torpedo boats, but the protection of the battleship against the submarine and its torpedo is a problem yet to be solved, as is illustrated by the present war. The modern submarine can approach, fire its torpedoes, and cruise away without coming to the surface, and is, therefore, immune

from gun-fire. As the submarine cannot be successfully attacked even by smaller craft, the battleship must adopt some effective form of defence. The torpedo net cannot be used while under way, as it would probably float up to the surface and would certainly prevent a high speed from being attained. Warship designers have proposed to armour the bottom of the ship, and this seems to be the only solution at present, although the weight of such armour must obviously cause a reduction of speed and armament. It is said that if a modern "Dreadnought" were clothed on the bottom with the necessary armour, and her fullness increased sufficiently to allow her to carry this armour, the only important effect would be to reduce her speed by two knots.

Suez Canal.—Owing to the possibility of the belligerent area during the present war covering the Suez Canal, it may be interesting to note its principal features. The canal is 161 kilometres (87 sea miles, or 100 statute miles) long. The navigable dimensions are now practically twice what they were in 1869, the superficial area having been increased from about 380 to 690 square yards in the ordinary channel, to 880 square yards in the numerous gares or crossing places, the dredging having been so carried out as to exceed the limits originally decided upon. From 1869 to 1875 the canal retained its depth of 26 ft. 3 ins., and its bottom width of 72 ft. throughout its length. The gares were 6¼ miles apart, each gare being about 1,100 yards long. From 1875 to 1884 the first improvements were made in straightening and widening the curves. During 1887–88 the canal was deepened by 20 ins., and the bottom width reduced to 59 ft. This extra depth allowed the transit of vessels with a draught up to 25 ft. 7 ins. From 1888 to 1895 the bottom width was increased to 108 ft. The result has been a diminution in the time of transit, which had already been shortened by the use of electric light at night. Ships could then pass one another at any point in the straight reaches in the canal instead of at the gares only. In 1898, owing to the increased dimensions of ships, larger gares were begun, some twenty in number, at an interval of three miles, each gare having an effective length of 820 yards, with approaches of 328 yards at either side. At the same time the depth of the channel was increased to 29½ ft. At present a draught of 28 ft. is allowed. The work of deepening the canal is steadily proceeding from El Ferdan to Suez, and the bottom width has been increased to 128 ft. The curves are also being improved, and a gare has been made on the small Bitter Lake.

Diesel-engined Warships.—Two ocean-going torpedo-boat destroyers will be shortly launched on the Clyde for the Japanese Government. These vessels are of exceptional engineering interest, because while the main propelling machinery is to consist of an installation of steam turbines, each will also have two Diesel engines of 1,200 horse-power for cruising purposes. The twin turbines will each be of 1,200 horse-power, and when the vessels are running at cruising speeds the twin screws will be driven by the oil engines, which it is understood will operate the propellers by means of solid shafts working inside tubular shafts. The Diesel engines, which are being built at Glasgow, are of the six-cylinder, four-cycle type, and they are designed to give the vessels a speed of from 13 to 14 knots. When the turbines are in use the speed will be about 34 knots. As the *Times* Engineering Supplement points out, the advantage of the oil engines for cruising lies in the great saving of fuel which will be possible, and the rapidity with which the vessels can be got under way. The destroyers are to be named "Kawakaze" and "Urakaze" respectively. There are no doubt further advantages beyond those mentioned above, in such a combination of machinery; for instance, when the boats are in the vicinity of the enemy they could proceed under oil-engine power, and so avoid the chance of betraying their presence, which would hardly be possible if they were emitting smoke from their funnels.

CORRESPONDENCE.

THE TRAINING OF INDUSTRIAL CHEMISTS.

In view of the movement for the advance of English industrial chemistry, may I point out the desirability of those who are thinking of taking up this branch of work undergoing thorough practical training in a laboratory after they have finished their purely scholastic course.

My experience is that whilst the usual school curriculum is admirably adapted for inculcating theoretical knowledge, the absence of a knowledge of the business application of theory often leaves much to be desired, with a consequent waste of time and energy, and I therefore strongly advise would-be technical chemists to undergo a practical course of instruction at the hands of technologists, whose business it is to apply theoretical deductions.

This is now so well understood by chemical manufacturers and others, that many prefer the laboratory-trained man to the mere student, however well he may have passed his examinations and high his degree. I have had B.Sc.'s and D.Sc.'s applying to me for work at the lowest rates of remuneration, whilst my own pupils, without such accomplishments, have at once stepped into excellent posts.

W. J. Dibdin.

OBITUARY.

Alfred Henry Baynes.—Mr. Alfred Henry Baynes died on October 16th at his residence at Northwood, Middlesex. He was born at Wellington, Somerset, in 1838, and educated at Devonshire

College, Bath. At first he was intended for the medical profession, but he was compelled by ill-health to abandon this purpose, and, coming to London, entered the accountancy firm of Messrs. Peto, Brassey and Betts. Sir Morton Peto, then head of the firm, was Treasurer of the Baptist Missionary Society, and at his request Mr. Baynes went to the Mission House to take charge of the accounts. He remained there for seventeen years as accountant, and subsequently, in 1878, he was appointed General Secretary, an office which he continued to hold till 1906. On two occasions he visited India and Ceylon, and it was largely through his instrumentality that the Congo Mission was successfully established.

Besides being an indefatigable worker and a skilful organiser, Mr. Baynes was a man of wide interests. He came of a scholarly family: one of his brothers, Professor Thomas Spencer Baynes, was editor of the ninth edition of the "Encyclopædia Britannica," while another, Canon R. H. Baynes, of Worcester, was the author of several well-known hymns. Mr. Baynes, who had travelled considerably, took a keen interest in geography, and was a Fellow of the Royal Geographical Society. He was also a member of the Royal Society of Arts for over forty years, having been elected in 1873.

GENERAL NOTES.

How to Supplant the Enemy Trade in India.—With reference to the paragraph under this heading which appeared in the last issue of the *Journal*, it is interesting to note that, according to the *Sind Gazette*, the French Consular authorities in India are pointing out to the leading importing firms in India the necessity for carrying the war into the economic field, not only with a view to preventing the pan-Germanic States from carrying on their export trade to any extent through neutral States, but also with a view to maintaining and developing the industries of the Allies, so that the latter may better be enabled to provide themselves with the resources necessary for carrying on to a victorious conclusion the present struggle for existence. The Office National de Commerce Extérieur, 3, Rue Feydeau, Paris, being a branch of the French Ministry of Commerce and Industry, has inaugurated an inquiry into the articles of German and Austro-Hungarian origin which can be replaced by French-made articles. The following list of nineteen classes of manufactures which France might supply is given: Chemical products, dyes, colours, etc.; earthenware, glass, crystal glass; textiles; linen dress materials and manufactured articles; paper and its applications; leather; articles made with hide and skin; furs, prepared or manufactured; gold and silver articles, jewellery, imitation jewellery; watches, clocks, etc.; machinery and mechanical appliances; tools and metal articles; furniture and articles made of wood; musical instruments; coaches, motor-cars, motor-cycles, bicycles; rubber articles; ornamental linen; scientific instruments and apparatus; inlaid work, fans, brushes, toys, etc.

Professional Classes War Relief Council.—An exhibition of arts and crafts and pictures will be held by the Professional Classes War Relief Council at 13, Prince's Gate on December 12th. The exhibition will be in three sections, as follows: (1) Exhibits to be sold for the benefit of the artists themselves. This section includes pictures, leather work, black-and-white sketches, metal work, enamels, art embroidery, etc. Five per cent. of the purchase price will be deducted for the benefit of the funds. (2) Exhibits presented by the artists to be sold for the entire benefit of the funds, and covers the same ground as section 1. (3) Toys and other articles made by professional women in the emergency workrooms. Five per cent. of all articles sold and orders taken to be deducted for the benefit of the funds.

Persian Rose-water and Attar of Roses.—There was a great increase in the export of rose-water from Bushire in the fiscal year 1912-13, 271 tons, against 189 tons in 1911-12. This product is obtained in one small district of Fars, between Bushire and Shiraz, where roses have been famous for many centuries, and there is extensive cultivation. Distillation of the rose petals and the manufacture of rough glass carboys and bottles is a special industry in the district. The total output of rose-water has been estimated at 400 tons, or 10,000 cases, but there is a large consumption in Persia itself. The yield of roses was larger than usual in 1913, but owing to lack of rain a vegetable product, which is used with certain local earths in manufacturing the crude green-glass carboys, was not obtainable in sufficient quantities, and there was a smaller output of rose-water than usual, which will probably be noticeable in the figures for 1913-14, when available. Hitherto there has been no attempt to place a Persian brand of essential oil (attar) of roses on the market in Europe, and the output has been limited to requirements in Persia and India, some 2,500 miskals or 320 ounces annually, but owing to the restricted Bulgarian crop and the favourable opportunity occurring, small experimental consignments were sent to London in 1913. Persian attar has marked qualities of its own, which make it quite different from the Bulgarian product.

The Coal Industry of Japan.—The most important coal district in Japan is the Island of Kyushu. The mines in this district are almost all owned or controlled by a company which, by agreement with its only large competitor, is able to control in large measure the prices asked for coal in Southern Japan. In the Hokkaido coal-fields many fine prospects are being discovered. Karafuto also is said to be rich in coalfields. The noticeable increase in the world's demand for

Japanese coal caused great activity in coal mining circles in 1913. Many new mines were opened up, and seams in old mines were prepared for operations; other seams abandoned as worthless were re-surveyed and profitable seams discovered, while the business of locating new coal outcrops was flourishing. In 1912, 19,638,755 tons of coal were mined throughout Japan; in 1913 this figure was increased to 21,300,000 tons. A heavy rise in the price of coal on the home market, due to the foreign demand, was one of the most disturbing economic problems confronting large manufacturing concerns throughout the year. The quantity of coal exported from Japan in 1912 was 3,440,347 tons, as compared with 3,839,881 tons in 1913. The amount of bunker coal supplied to Japanese and foreign vessels in Japanese ports was 2,471,000 tons in 1912, and 2,676,000 tons in 1913. Cheap Chinese coal is imported to take the place of the high-priced Japanese coals that are exported.

MEETINGS OF THE SOCIETY.

Ordinary Meeting.

Wednesday evening, at 8 o'clock:

December 16. Sir William de Wiveslie Abney, K.C.B., D.C.L., D.Sc., F.R.S., "Testing Pigments for Permanence of Colour." Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock:-

December 17. Dr. F. Mollwo Perkin, F.I.C., F.C.S., "The Indian Indigo Industry." Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., will preside.

Papers to be read after Christmas:-

F. Vincent Brooks, "British Lithography in 1915."

Hon. John Collier, R.O.I., "Portrait Painting." Lord Sanderson, G.C.B., K.C.M.G., will preside.

Octavius Charles Beale, Chairman of the Australian Manufacturers' Association, "Imperial Industrial Development after the War."

Thomas Worthington, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. Thorne Baker, "The Industrial Uses of Radium."

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. Hulme, "Patent Law."

H. M. Thornton, "The Industrial Uses of Coal Gas."

D. Y. Cameron, A.R.A., R.E., "Etching."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

William Poel, "Shakespeare's Profession."

Arthur Wilcock, "Designing for Textiles."

J. A. Hunter, "The Textile Industries of Great Britain and of Germany."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Edward R. Davson, "Colonial Sugar Development."

Major E. H. M. Leggett, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda."

Henry John Elwes, F.R.S., "Nepal."

Captain Sir George Duff Dunbar, Bart., I.A., "Tribes of the Brahmaputra Valley."

Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army."

M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 21, February 18, March 18, April 15, May 13.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:

February 2, March, 2, 30, May 4.

Cantor Lectures.

Monday evenings, at 8 o'clock:-

R. A. Peddie, Librarian, St. Bride Foundation Typographical Library, "The History and Practice of the Art of Printing." Four Lectures.

Lecture IV.—December 14.—*The later history of colour printing.* Rise of chromo-lithography—Chromo-xylography The three-colour process—Collotype—Photogravure and its combinations—The offset process.

Dr. F. Mollwo Perkin, F.I.C., F.C.S., "Oils, their Production and Manufacture." Three Lectures.

January 18, 25, February 1.

M. H. Baillie Scott, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Fothergill Lectures.

Monday evenings, at 8 o'clock:—

Professor Vivian B. Lewes, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

February 15, 22, March 1.

JUVENILE LECTURES.

Wednesday afternoons, at 5 o'clock:—

H. PLUNKET GREENE, "How to Sing a Song." Two lectures, with vocal illustrations.

January 6, 13.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. R. A. Peddie, "The History and Practice of the Art of Printing." (Lecture IV.)

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Mr. E. W. Maunder, "The Principles of World Empire."

Engineers, Cleveland Institution of, Corporation-road, Middlesbrough, 7.30 p.m. Mr. J. H. Whiteley, "A Study of Cast Steel."

Electrical Engineers, Institution of (Newcastle Section), Mining Institute, Newcastle-on-Tyne, 7.30 p.m. Mr. C. J. Beaver, "Cables."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 8 p.m. (Graduates' Section.) Mr. C. B. Dicksee, "The Conditions Governing the Power of Petrol Engines."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Messrs. A. Young and L. O. Mathews, "The Report of the Land Enquiry Committee on the Acquisition of Land."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Captain H. A. Edwards, "Frontier Work on the Bolivia-Brazil Boundary."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Professor W. C. F. Anderson, "Montenegro."

Medicine, Royal Society of, 1, Wimpole-street, W. Section of Dermatology, 5 p.m. Dr. K. Sibley, "Case of Angiokeratoma." Other cases will be shown.

Historical Society, 7, South-square, Gray's Inn, W.C., 5 p.m. Dr. G. W. Prothero, "The Causes of the Anglo-German Hostilities in 1914, from the Historian's Point of View."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Discussion on Mr. H. K. Dyson's paper, "Shear and Problems arising therefrom."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 8 p.m. Mr. T. A. Rickard, "Persistence of Ore in Depth."

FRIDAY, DECEMBER 18...Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Address by the Marquis of Graham (President), on "The War and Engineering."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 8 p.m. Papers by Messrs. W. C. Acfield (Midland Railway), L. P. Lewis (Caledonian Railway), V. L. Raven (North-Eastern Railway), W. A. Stanier (Great Western Railway), and W. Willox (Metropolitan Railway), on "Audible and other Cab Signals on British Railways."

Journal of the Royal Society of Arts.

No. 3,239. VOL. LXIII.

FRIDAY, DECEMBER 18, 1914.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

CANTOR LECTURES.

On Monday evening, December 14th, Mr. R. A. Peddie delivered the fourth and final lecture of his course on "The History and Practice of the Art of Printing."

On the motion of the Chairman a vote of thanks was accorded to Mr. Peddie for his interesting course.

The lectures will be published in the *Journal* during the Christmas recess.

INDIAN SECTION.

Thursday afternoon, December 17th; Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., in the chair. A paper on "The Indian Indigo Industry" was read by Dr. F. Mollwo Perkin, F.I.C., F.C.S.

The paper and discussion will be published in a subsequent number of the *Journal*.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 6th and 13th, 1915, at 5 p.m., by Mr. H. Plunket Greene, on "How to Sing a Song."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

Wednesday, December 16th, 1914; Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Vice-President and Chairman of the Council of the Society, in the chair.

The following candidate was proposed for election as a Fellow of the Society:—

Soule, President Andrew McNairn. Sc.D., Ph.D., State College of Agriculture, Athens, Georgia, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Smith, Rev. Professor Samuel George, D.D., LL.D., Ph.D., St. Paul, Minnesota, U.S.A.

Tyrer, Thomas, F.I.C., F.C.S., 14, Sandwell Mansions, West End-lane, N.W.

The Chairman said there was no need for him to introduce such a distinguished member of the Society as Sir William Abney. Sir William had read many papers before the Society. As an expert in all matters connected with colour, whether in relation to photography or to other forms of art, Sir William's reputation was world-wide. He (the Chairman) remembered that some years ago the matter of testing pigments for their permanence and colour was the subject of some amount of agitation amongst artists, and experiments were made then, principally, he thought, by Sir William himself; but the conclusions formed at that time were not absolutely accepted, and since then further experiments had been carried out by the author, and it was with regard to those particularly that Sir William was going to address the members that evening.

The paper read was—

TESTING PIGMENTS FOR PERMANENCE OF COLOUR.

By Sir William de W. Abney, K.C.B., D.C.L., D.Sc., F.R.S.

It is some twenty-eight years since the late Dr. W. J. Russell, F.R.S., and myself were asked by the chiefs of the Science and Art

Department to investigate the causes of the fading of water-colour drawings when exposed to light. There were, and are, in the Victoria and Albert Museum collection of water-colours many samples of the injurious effects which exposure to light have had on them.

Soon after we started our investigations the press announced that such an inquiry was under way, and a resolution from the Royal Society of Painters in Water Colours was then sent to the Science and Art Department, urging "the desirability, in the interests of water-colour painters, of the appointment of a water-colour painter in association with Dr. Russell and Captain Abney in the work of investigating the effect of light of various colours upon water-colour pigments." This resolution was considered, and the Department requested the Royal Water Colour Society and the Royal Institute of Painters each to appoint two members to a committee which it proposed to form with a view that we should keep such a committee informed as to the methods of investigation we were adopting. "The committee, with this information before them, would be in a position to judge whether there were any further points they would desire to suggest for investigation, or whether there is any investigation which the committee would themselves wish to carry out."

The committee appointed was as follows:—Sir F. Leighton, P.R.A., chairman, Mr. L. Alma Tadema, R.A., Mr. T. Armstrong, Mr. Sidney Colvin, Mr. Frank Dillon, Mr. Carl Haag, Sir James D. Linton, Mr. E. J. Poynter, R.A., and Mr. Henry Wallis, with Mr. Arthur Torrens as secretary. The scheme that we had thought out was submitted to the committee and unanimously approved, and they did not propose any investigation of their own. For nearly three years we continued our experiments, and in June, 1888, we made a report of which the above-named committee also approved. This was issued as a Parliamentary paper to both Houses of Parliament. A certain number of reviews and various letters appeared in the press on the subject of the report. The criticisms were mostly of a kindly nature. The facts brought out by the results of our numerous and tolerably exhaustive experiments were not questioned. In one or two cases our interpretation of them was criticised. After a month or two our investigation did not call forth much further notice, and, like the fate of most Parliamentary reports, it remained to a great extent unheeded, except, perhaps, by artist colourmen. Another unofficial committee was formed by some persons interested in the subject of Fading, and the results of their experiments were published from time to time. If I remember rightly, they in no ways impugned the results of our experiments.

There are so many colours in an artist colourman's list that the trial as to the stability of all of them would have increased the number of experiments manyfold. To enable us to judge which were the most necessary to proceed with, the Science and Art Department obtained from forty-five of the principal water-colour artists lists of the colours which they individually employed. From these lists we selected the pigment colours, the stability to light of which we concluded ought to be investigated.

Twenty-five years have passed, and I shall not be guilty of indiscretion if I say that we found that nearly all the forty-five were using one or more of what may be called fugitive colours. It would have been interesting if a year after our report had been issued we could have had fresh lists before us of the pigments they then severally used, to see what changes had been made. Some, no doubt, would have thought as one artist did, who argued that whilst some of A's colours had been proved to fade, yet all of B's were quite safe. Almost a new generation of artists is living now, and as artists are not as a rule given to reading scientific works, it is quite possible that the report on the fading of water-colours may be unknown to them, especially as it is "buried" as a Parliamentary paper. It is for this reason that I wish, in a way, to revive if possible the interest in the subject by bringing it before the Royal Society of Arts, and to explain a method of testing any pigment for fading in a short time, instead of having to wait for a year or two before results could be obtained. There are various new water-colour pigments placed before the public from time to time, and it is these which require a simple test.

In reference to the younger generation of water-colour artists, I may say that even older painters sometimes require information.

It was not very long ago that on arrival at a certain foreign capital I paid a visit to an artist friend whose drawings are well known and appreciated in Europe and America. On my arrival I was shown up to the studio and found my friend for the moment the picture of despair. He was extracting pictures from a packing-case which had been returned from another capital after being exhibited for a couple of months the previous autumn.

He pointed out to me that a whole series of those which had been hung near the skylight of the exhibition room had lost colour in parts. Their freshness had gone, though they were still beautiful works of art. Questioning him as to what colour had faded, I found that it was vandyke brown, which he used to give tone to some of his delicate colour-washes. He only knew me as an amateur painter, and was unaware that the question of the fading of colours had been one of my hobbies. I told him the result of our experiments, and furnished him with a copy of our report. On a subsequent visit I found him radiant once more, having obtained a substitute for his vandyke brown which was permanent. I may say that he grieved principally over the fact that his clients had pictures of his which might behave or have behaved as those did which were exhibited.

My friend being a foreigner, I could not blame him for being unacquainted with our experiments on safe colours. Nearer home I have found published a list of colours used by a very celebrated artist. That list contains the names of some which he should have placed on the "black list." One has to imagine what may be said of his pictures by his clients in a few years to come. I have often inquired of my numerous artist acquaintances as to the composition of the palette they use, and in not a few cases have I given warning as to colours which ought not to be used. [I should recommend to any one who cannot paint, but thinks he can, to use every colour which is not "safe," as the productions will eventually find their way into the wastepaper basket.]

I trust I may be allowed to recapitulate briefly the conditions most favourable for the fading of pigments, and those under which the fading of some of them is highly, to say the least, improbable to occur.

Speaking generally, every pigment absorbs or abstracts rays of the spectrum which it does not reflect, and it is the collection of the reflected coloured rays that gives the colour of the pigment. Each particle of a pigment is composed of a very large number of molecules, and these molecules are formed of several atoms, held together by attraction to one another. The rays of light absorbed by the pigment may by their vibratory motion shake away from the molecules one or more of the atoms, decomposing the molecules, and thus change the particles of the pigment. This change in composition is shown as fading. Like the silver salts in photography if a body is in contact with the pigment, which can take up the atoms of the shaken-off molecules greedily, then the fading in a given time will become more rapid. Such a body is found in the moisture in the air, so that a damp pigment fades more readily than a dry pigment. In the case where the atoms of the pigment, even with moisture present, refuse to be removed from the molecule, there is no fading.

It was owing to observations on the salts of silver, which behaved as just described, that our experiments on pigments were started. There is always moisture in the atmosphere, so that if a pigment is exposed to light under ordinary atmospheric conditions it is liable to fade; if it will fade at all the fading will show itself eventually. In our experiments the light employed was sunlight and skylight. The pigments exposed had various depths of colour, No. 1 being the lightest and No. 8 the darkest.

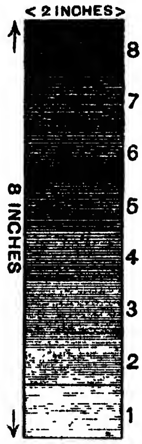

FIG. 1.

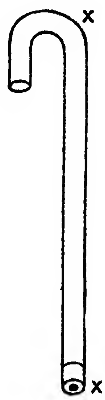

FIG. 2.

Half of the paper washed with the varying shades of colour was covered up with black paper, and the light had free access to the other half. The papers were exposed in glass tubes bent over at one end to form a hook. There was a perpetual change of air in the tubes.

The annexed table shows the pigments which were exposed to light in these tubes, and the results of the exposure. The last thirteen showed no signs of fading. The first thirteen are really unstable, and the whole list is placed approximately in the order of instability. The next thirteen are much less unstable:—

Colour.	Composition according to Winsor and Newton.
Carmine . . .	Lake prepared from cochineal.
Crimson lake .	Lake prepared from cochineal.
Purple madder .	Lake prepared from madder root.

Colour.	Composition according to Winsor and Newton.
*Scarlet lake.	Lake prepared from vermilion and crimson lake.
†Payne's grey	Indigo crimson-lake and carbon black.
Naples yellow	Mixture of zinc white and cadmium yellow.
Olive green	Quercitron lake, bone brown, and ultramarine.
Indigo	Extract from the indigo plant.
Brown madder	Lake prepared from madder root.
Gamboge	A preparation of gum resin.
Vandyke brown	Native earth prepared for painting.
Brown pink	Lake made from quercitron bark.
Indian yellow	Prepared "purree" from India.
Cadmium yellow	Sulphide of cadmium.
Leitches blue	Mixture of Prussian blue and cobalt.
Violet carmine	Lake obtained from root of anchusa.
Purple carmine	Lake obtained from root of tinctoria.
Sepia	From the cuttlefish bags.
Aureolin	Double nitrite of cobalt and potassium.
Rose madder	A lake from the madder root.
Permanent blue	A pale variety of French ultramarine.
Antwerp blue	Prussian blue and alumina.
Madder lake	Same as rose madder.
Vermilion	Mercuric sulphide.
Emerald green	Aceto-arsenate of copper.
Burnt umber	Calcined raw umber.
Yellow ochre	Native earth.
Indian red	A variety of iron oxide.
Venetian red	Artificially prepared sesqui-oxide of iron.
Burnt sienna	Calcined raw sienna.
Chrome yellow	Normal chromate of lead.
Lemon yellow	Chromate of barium.
Raw sienna	Native earth.
Terra verte	Native earth.
Chromium oxide	Chromium sesquioxide.
Prussian blue	Ferro-cyanide of iron.
Cobalt	Alumina tinctured with cobalt oxide.
French blue	Artificial ultramarine.
Ultramarine ash	Extract of lapus lazuli.

Looking at the composition of the last thirteen permanent colours we cannot fail to notice that they are all native earths or oxides of metals, with one or two exceptions. In fact, all have a mineral basis, whilst the remainder of the list which have the most tendency to fade are mostly organic derivatives.

* Scarlet lake more recently prepared is now made from vermilion and alizurin crimson.

† Payne's grey is now made from carbon black ochre and French ultramarine. Both Payne's grey and scarlet lake should now be much more permanent.

It must be recollected that the light used in obtaining these results was of the most intense nature, and not that to which ordinarily water-colour paintings would be exposed.

The second thirteen colours are probably colours which would not fade in any ordinary light. It must, however, be remarked that when mixtures of colours are employed those colours which are more or less fugitive have a greater tendency to fade than when tested alone. For instance, in a mixture of indigo and Indian red the indigo fades more easily than the indigo does when unmixed. Russell and myself proved this by experimenting with thirty-four mixtures, such as were often used by artists.

The case which I mentioned of the rapid fading of vandyke brown in the light from the sky was probably due to the vandyke brown being used mixed with other colours.

It may be as well to state here we found experimentally that practically every coloured pigment exposed to light *in vacuo* declines to fade, and the same may also be said of pigments exposed in perfectly dry air or oxygen, a condition which is non-existent in the atmosphere in which pictures are exposed to light. The presence of moisture is always required to effect a change in colour, and we also found that the bluer the light to which colours are exposed the more rapidly, in most cases, will the fading take place.

A reference must here be made to the effect of the light from the sky on pigments exposed for nearly two years in a frame in a window with north light. The following colours were in the frame:—

Antwerp blue	Prussian blue and vandyke brown
Prussian "	Prussian blue and gamboge
Leitches "	Prussian blue and Indian red
Indigo	Indigo and vandyke brown
Gamboge	Indigo and burnt sienna
Brown pink	Indigo and Indian red
Indian yellow	Rose madder and raw sienna
Naples "	Antwerp blue and raw sienna
Lemon "	Vermilion and chrome yellow
Vandyke brown	
Venetian red	
Crimson lake	
Vermilion	
Rose madder	
Carmine	
Prussian blue and burnt sienna	

Our report on the effects of this moderate daylight was as follows:—

Of the single colours, gamboge, indigo and Naples yellow had slightly faded; brown pink

had faded perceptibly to 6 (the deepest shade but 2); carmine had *bleached* to 3; vandyke brown had faded to 1 and was fainter to 4; and crimson lake had faded to 5; and all the darker shades had become paler. In mixtures one of Prussian blue and burnt sienna that had changed, the blue had faded. With Prussian blue and vandyke brown, and with indigo and vandyke brown, the vandyke brown had faded. With Prussian blue and gamboge, the gamboge had slightly gone in No. 1 and all shades had become browner. With indigo and gamboge, all the shades had become paler throughout. With indigo and Indian red the indigo in No. 1 had gone entirely and partly in all tints. The other colours both single and mixed, had not changed.

This experiment confirms the results which had taken place in strong light. We may, therefore, take it that the list of fugitive and stable colours we have given is the same in feebler light as it was in sunlight. From the permanent thirteen colours we have given, and from the thirteen semi-fugitive colours, we can form a good gamut for the water-colour artist.

Various artifices from time to time have been proposed for preventing the fading of pictures in light. A novel and effective one theoretically was to make the frame into a vacuum chamber. But so far as I know there were practical difficulties existing which prevented its general adoption. Recently a glass has been proposed which is said to prevent chemically the active rays from reaching the picture. I have roughly and not exhaustively tried a specimen of this glass, and exposed fugitive pigments beneath it to light this autumn. I have not found that it prevented the fading of the colours I tried, and I should hesitate to adopt it myself. But I hope that others will try its effect. If it is proved efficient it would be a great boon, and the list of fugitive colours might then be of no use. I have said that the blue light (which includes the violet) is that which is most chemically active. I found that if a skylight was glazed with signal-green glass and an orange in right proportions to make a white light by their mixture, the colours of pigments appeared as in ordinary white light and the chemically active rays were cut off. The committee I mentioned in my paper satisfied themselves that such was the case and the Raphael cartoon gallery was so glazed. The public seemed unaware of the peculiar mode of glazing.

May I be allowed to become a little personal for the moment? Having studied the theory of colours from a scientific point of view for more years than I like to remember, when I retired from the Civil Service some eleven years ago I took to painting in water-colours as an occupation. Naturally I endeavoured to get a gamut of colours which should be sufficient in their range and at the same time as permanent as possible. My colour-box now consists of:—

Vermilion	Cobalt
Light red	French blue
Rose madder	Antwerp blue
	Cyanin blue
Aureolin	Violet cobalt
Yellow ochre	
Raw sienna	(An imitation and permanent) vandyke brown
Cadmium yellow	
Madder ,,	(An imitation and quasi-permanent) brown madder
Lemon ,,	
	Turner's brown
Emerald green	Burnt sienna
Viridian	Neutral tint (from my own formula)
Hooker's green (A new mixture)	
Sunny green	Ivory black

All these colours are either in the list of the thirteen permanent colours, or come near them in the next thirteen. None of the colours is in the first thirteen, which, as already said, I class as fugitive colours.

Before adopting these colours I was anxious to see how the mixtures imitating colours with known names would stand the light. A year or two after the report had been published I determined to try if a short cut could not be found to test the permanency of any colour. Some experiments I had made with certain photographically-produced colours led me to think that the action of light on pigments in the presence of moisture might be a secondary action, and that the fading might be due to the formation of some oxidising agent produced by the light on moisture in the presence of oxygen. It had been proved in our report that the exclusion of all air from the colour prevented fading, and that colours did not fade when *dry* oxygen was in contact with them, and that only when there was the addition of moisture did the fugitive colours fade. It appeared to me that if oxygen were ozonised in the presence of moisture, the action might be the same as when light was acting with no added ozone present: in other words, that light itself tended to produce an ozonised atmosphere in the presence of moisture and that it was this which caused the fading.

To test this, strips of the same colours as those which were exposed to the light were moistened and placed in a tube, through which ozonised oxygen was passed in a slow current. The oxygen was ozonised by an ozone tube connected with a coil. As I anticipated, there was a fading of those colours which were affected by light. I have already given the list of single colours which were tried, in their order

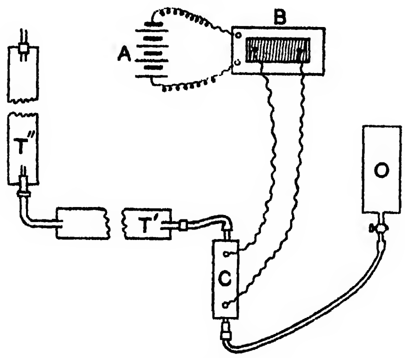

Fig. 3.

of "light" stability. Practically this same list is here repeated in the following table, but it also shows the times of exposure to the ozone current which were required to cause fading or destruction of those colours which light had been able to alter. The times given as necessary for ozone to act are approximately the relative sensitiveness to fading by the method described.

Pigments in the order of fadings by light	Time of exposure to fade in damp ozonized air.	
	h.	m.
Carmine	0	10
Crimson lake	0	30
Purple madder	0	20
Payne's grey	1	0
Naples yellow	0	45
Olive green	1	5
Indigo	0	40
Brown madder	2	10
Gamboge	0	50
Vandyke brown	1	15
Brown pink	0	30
Indian yellow	4	0
Cadmium yellow	4	0
Violet carmine	4	0
Aureolin	Unchanged.	
Rose madder	4	0
Permanent blue	3	30
Vermilion	Unchanged.	
Emerald green	0	45

Pigments in the order of fadings by light.	Time of exposure to fade in damp ozonized air.	
	h.	m.
Yellow ochre	Unchanged.	
Indian red	,,	
Venetian red	,,	
Burnt sienna	,,	
Chrome yellow	,,	
Raw sienna	,,	
Terra verte	,,	
Chromium oxide	,,	
Cobalt	,,	
French blue	3	30
Ultramarine ash	Unchanged.	

The same colours were exposed to dry ozonised oxygen, all moisture being excluded. The paper and pigment were carefully dried, and the oxygen had to bubble through a series of bulbs containing strong sulphuric acid, to absorb any moisture which might have been in the oxygen. In no case did the dry ozonised oxygen have any action on the pigments. The most fugitive came out of the exposure-tubes unaltered.

This, be it remembered, was the same when the exposure to light took place in dry oxygen. The pigments remained unchanged.

This experiment proved that unless moisture were present with the ozonised oxygen the test did not work.

It will be noticed that eleven of the first thirteen colours which in our list showed no change under the influence of light, were taken, and only one of them, French blue, showed any change under the influence of ozonised oxygen and moisture, and that was very small. Of the other twenty-six colours only twenty-three were experimented with, and all of them showed an alteration. Of the second thirteen in the list, seven were tried and all proved to be fairly stable colours, aureolin and vermilion, which under the action of light blackened, showed no deterioration; the others, after an exposure to the ozone, showed slight deterioration after about four hours. Of the thirteen most fugitive colours in the list, scarlet lake was omitted. Brown madder and Indian yellow appeared more stable than they did when exposed to light, the remainder followed very fairly the order of fugitiveness given in the list.

Mixtures faded under the influence of damp ozone more rapidly as a rule than did the fugitive colours by themselves. Where one of the colours was stable the fugitive colour completely disappeared, and where both were fugitive—as, for instance, a mixture of indigo and gamboge—both disappeared.

It might be thought that peroxide of hydrogen, which is used for altering the colour of

hair and for other purposes, might be a substitute for the ozone treatment. So far I have found it quite inoperative in regard to pigments such as have been tested.

Returning for an instant to my own water-colour box, I show the results of the ozone treatment. The only case where any fading has taken place in any of the colours is that of rose madder, which had a most prolonged exposure. It will be noticed that where I have replaced a colour by a mixture having the same tint (*e.g.*, Hooker's green, made of Prussian blue and aureolin), the colour is a stable one, since both the mixing colours are stable. I have brought a few of the really unstable washes to show you, and you can judge of the effect of the ozonised damp air upon them.

With oil paints the ozone test has so far, with me, been unsuccessful. The ozone seems to attack the medium, as the colour is so successfully locked up in it that very little effect is produced, even with the most fugitive colours. This is not what takes place when light acts on oil colours, for in a series of experiments (not yet published) made with them the same final results were obtained as with water-colours.

So far I have confined myself to water-colour washes, but the same method of experiment gives an answer at once as to whether a wallpaper will remain unaffected by light.

In my own house I have unfortunately had wallpapers which looked pretty and well suited to the rooms, but in the course of two or three years all the prettiness had gone, though a pattern remained. Of some of these papers I had spare rolls, and I tested them with the ozone treatment, and found that it gave the same class of fading as that which the exposure to light had given.

It is quite easy to diagnose whether a wallpaper will stand the light, and I always try and test them before I make a final choice. It is in the delicate tints that fading takes place. Where a paper is heavily coated with a pigment which, when applied more thinly, will fade, it may stand the light for a considerable time before being found out. I show numerous kinds of wallpapers which have been submitted to the test. In some cases the fading is slight but quite marked; in others the fading is much more marked, more especially with certain kinds of papers which have a green tint in them. In a good many cases the papers have been on walls of a room, and the fading is similar to that caused by the ozone.

The test for permanence of colour can be applied to ladies' dresses. Summer dresses are very often of beautifully delicate shades, and have parasols to match the dresses. A few inches of the material of a dress will be sufficient to indicate what may be expected to happen in a summer light. I believe it has often been remarked that at the seaside dresses "go" much more rapidly than at an inland place. The reason for this may be that there is more ozone and moisture at the seaside than there is inland. Ladies also inform me that abroad a dress may not fade in bright summer light when it inevitably would do so in our island. The air on the Continent is, as a rule, drier, and it may be that the want of moisture is the cause of the apparent stability of the colour. Wools and cotton-stuffs can be subjected to the same tests, but where the colours are on paper the tests are more rapidly carried out. The mordants often make the colouring matter more stable than it is on paper. Those dyes I have tried are on the dyed material.

DISCUSSION.

PROFESSOR J. M. THOMSON, F.R.S., in opening the discussion, said the matter was of very great interest, and it was very complicated. Looking at it from the chemical point of view, he did not think, so far as mineral colours were concerned, there was much difficulty; they were comparatively permanent. But with colouring matters of organic origin the reactions were very complicated. He thought it might be taken that the action in those cases was generally one of oxidation—he meant when pictures were exposed (as they usually were) to light, not when they were in a bad atmosphere. If they were in a bad atmosphere then other reactions were produced. He considered it was an oxidising action, that oxidising action taking place in the presence of moisture. If even the simple colours were taken—the action under strong light of oxygen upon those colours in the presence of moisture, or even in the presence of peroxide of hydrogen—it would be found that decay or bleaching would occur. The most important question was, how could that be prevented? People generally put up a water-colour picture in the most favourable conditions to produce bleaching. They put it up behind a glass plate, with a very imperfect backing as a rule, and when the sun shone upon that picture the glass got heated, the picture itself got heated, and the paper upon which the picture was put was acted on by the chemical agents equally with the colours. The paper itself had therefore to be considered. That paper, under most conditions of British weather, was moist, and the sun at once produced behind the glass an oven of moisture, and heaven only knew what actions were going

on between the partial decompositions proceeding in presence of moisture and the colours. One result of the author's and Dr. Russell's work had been to cause artists to look much more closely after their paper. A great deal of good scientific work had been done for artists, but he had been appalled by the apathy of the artists in taking advantage of that work. Many artists were quite ignorant of the materials they used. He desired to ask the author one question about Prussian blue. It was known that Prussian blue, when exposed to a bright light probably with the presence of moisture, faded, and a brown effect was obtained. He had two large water-colours in his collection which depicted originally beautiful bluey-green spring scenes. They were now certainly very pretty pictures; but they were autumn scenes – they were all brown. He had taken those pictures away from exposure by putting them into a dark drawer for years, but they not come back to their original colouring. He had read somewhere that a faded Prussian blue water-colour would come back if put in the dark. He had not actually experimented analytically upon those pictures, but he had taken Prussian blue and exposed it to light for a very long time. It partially faded As far as he could make out, the result of that was that it had gone into some peculiar iron compound. Therefore, he could not think the pictures would ever come back again to their original green colouring. Apparently, water-colours must be kept in a perfectly dry condition. He had no doubt that the whole of the action upon those pictures was due to the moist oxygenation which went on. It had occurred to him, while listening to the paper, that one way of preserving water-colours might be by putting them under a blue, a red, and a yellow glass, but they would not be much use to look at. He feared the only way for collectors to keep water-colours perfectly safe was to keep them perfectly dry, and in portfolios.

Mr. J. D. Crace said, in reference to Prussian blue, he might quote the experience of William Simpson, a very distinguished artist with a very inquiring mind. That gentleman had told him that he had put up on his shutter a piece of water-colour paper, across which he had painted strips with the different colours he ordinarily used, covered over half of it, and left it exposed to light for more than ten years. Some of the results were very curious. The yellow chrome, which he had always looked upon as one of the permanent colours, had distinctly faded; the Prussian blue, which he had always thought a very uncertain colour, had faded a little, but still kept its colour; and the part which was covered up was perfectly good as when it was first laid on; the blue of it had not changed, but only faded. That led him to think that perhaps Professor Thomson's pictures were painted with indigo. One or two of the items in the paper had rather astonished him. He had always looked on Hooker's green as a not very trustworthy composition. There was no question that damp enormously accelerated the fading of colour; and where pictures were under glass it was very necessary to protect them from dirt. He considered it very much helped the preservation of colour if the picture was in a sunk mount and not in contact with the glass, as in that case it would escape some of the consequences of condensation. He considered that a water-colour painted with a careful palette had a long life before it. Many of the pictures painted from fifty to eighty years ago were still so good as to distinguish themselves among modern paintings. It was largely a question of care. The water-colour not being locked up in oil it was so much the more easily influenced. On the other hand it retained purity and an absence of the discolouring of the vehicle, which in itself preserved an atmosphere and charm of colour which oil pictures could never possess.

Mr. Arthur Rackham said he was very puzzled to notice that the author had put chrome yellow among the permanent colours. There was a general impression amongst artists and artists' colourmen that cadmium was much more permanent than chrome. He wondered whether there had been a mistake in the paper, because chrome was now universally condemned. He also noticed among the permanent colours madder yellow. He did not quite know what that was, and would like to hear more about it. Light red was not among the colours at all, and he imagined that was quite a sound colour. He would also like to hear of a test for Chinese white Chinese white ought to be zinc white and permanent so far as light went, but there was no doubt that sometimes it was adulterated with lead, and darkened. He had also heard that the madders faded when mixed with blacks, the blacks being, he supposed, carbon colours, and the madder a vegetable colour, and tending to fade in the presence of charcoal. He would like to know whether that was a real danger or whether it was a chemist's splitting of straws, because one would like to use rose madder, and he did not know whether the modern substitutes, the aniline colours, were really as permanent as rose madder.

Mr. W. B. Ferguson, K.C., inquired if the author had experimented on the effect of the electric arc light on colours, and whether the influence of arc light was much the same as that of sunlight. Many people were not always in a position to command the use of an ozone-making apparatus, and many had utilised an arc light. Would it be possible to use that for testing, say, a wallpaper? To damp a certain piece of the wallpaper, keep a certain piece dry, and then to expose the damp piece for some time to the arc light? Perhaps the author would say whether such a method might be used as a practical means of testing the permanence of wallpapers and other pigments.

Mr. Charles Harrison said if anybody asked him what pigments were likely to be permanent

he would reply: "If you want pigments that are fairly permanent for ordinary living conditions, select those pigments which have been produced at a temperature somewhere about dull red heat." It struck him that there were three classes of pigments:—(1) Those which had a tendency to be acid in their composition; (2) those which had a tendency to be neutral, neither acid nor alkaline; and (3) those which had a tendency to be basic. It followed that if a man mixed an acid pigment with a basic pigment in conjunction with moisture and other atmospheric influences, decomposition must be expected, apart from light. With regard to water-colours, he would like the author to give an indication as to the usual kind of mediums or binders used by artists. He desired to call the author's attention to the question of heat. Vermilion was classed as a permanent pigment. He (the speaker) was not so sure he would call it that, because at a temperature of 50° C. it would gradually turn brown. He had come to the conclusion, after some study of the subject, that the only really suitable pigments were those which neither tended to be acid nor alkaline, but which were absolutely neutral in their chemical action: also they must be produced by a temperature about red heat. Zinc oxide was perhaps excluded, that would be quite safe, provided it did not come into contact with acid gases.

MR. JOSEPH W. LOVIBOND said amongst other things it had occurred to him that artists were rather hardly used in being blamed for not utilising the scientific information which was available. The standpoints of the artist and the scientific man were quite different, and their nomenclature even had little in common. There were other points to be considered: for instance, many colours had more than a single constituent, and one might be permanent and the other fugitive, so that the fading of the fugitive constituent produced a colour change. He considered these matters might be settled by research, and referred to methods by which the needed information might be obtained.

MR. THOMAS A. DAVIDSON, F.C.S., said he was not quite clear as to the construction of the apparatus which the author had described for testing the action of ozone on certain pigments. Were the tubes in which the colours had been exposed made of glass and transparent, and had the special intensity of light been considered?

MR. T. R. BURTON (the *Oil and Colour Trades Journal*) said that at the recent International Congress of Applied Chemistry, held at New York, Dr. Toch had made some observations which were very pertinent to the present lecture, and perhaps he (the speaker) might be allowed to quote them. Dr. Toch had said that water-colours were much more permanent, as a rule, than oil colours, because in the latter the medium introduced a greater possibility of chemical complications. He also, said that Prussian blue was among the most permanent of pigments; cadmium yellow was better than chrome; he classified silver white as permanent; the iron colours as liable to undergo chemical change due to oxidation, particularly in combination with oil; and vermilion he classified as not permanent.

THE CHAIRMAN (Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.), in closing the discussion, mentioned that he first learned to paint under John Callow, the brother of the better known William Callow, and his method of instruction was, he (the Chairman) always thought, an exceedingly good one. At the beginning he taught his pupils to paint with three colours only cobalt, lake, and yellow ochre. After a more or less imperfect mastery of those three colours the pupils were allowed to go on to three others—another red, blue, and yellow, that was to say burnt sienna, gamboge, and indigo The effect of John Callow's teaching no doubt was excellent, because the pupils did learn more or less how to use those six colours. The materials, however, which John Callow recommended left a great deal to be desired, for out of those six paints twice had been condemned as wanting in permanence. He (the Chairman) had found that lake was impossible to use if there was any chance of water-colours being exposed to strong light or to very great moisture; in fact, lake, certainly in combination with other colours, always turned black. Personally, he had no reason to complain, as far as his experience went, of water-colour sketches fading, and some of his had been exposed to light for thirty years. What he had found, rather than fading, was the tendency for colours not to intensify, but, as he believed, to oxidise and to turn black. That was the case not only with lake, but very much also with Chinese white. He thought, on the whole, the possessors of good water-colour pictures might fairly congratulate themselves that their pictures did retain the vividness of colour which was the original beauty of them. Speaking simply of life in the tropics—and he had been forty years in India—he thought, certainly that for those who aspired to keep a record of their lives in the tropics by means of artistic efforts, water-colour was decidedly the medium they should select rather than oils.

THE AUTHOR, in reply, said he had so many points to answer that he hoped he would be forgiven if he missed any. He was surprised to hear from Professor Thomson that the Prussian blue in his pictures had become brown. Was Professor Thomson quite sure it was Prussian blue? An artist did not often use pure Prussian blue, as it was much too violent a colour. If there was a moderate amount of fading of Prussian blue in a picture, if it was put away for a month in the dark the original vigour returned. If the Prussian blue went beyond the first fading, as might be the case with Professor

Thomson's pictures, then oxide of iron might form. He should feel inclined to say that Professor Thomson's pictures were painted with indigo. One speaker had said he thought Hooker's green was a dangerous colour. He (the author) quite agreed, because it was composed of Prussian blue and gamboge. Nobody in their senses would use gamboge of necessity, because it was proved to fade. But in the paper he had referred to a new sort of Hooker's green, in which the gamboge was replaced by aureolin. That exactly matched the Hooker's green, and was permanent. Another gentleman had expressed surprise at seeing chrome yellow put in the list of permanent pigments. It was perfectly true that Dr. Russell and himself tried chrome yellow. In the artists' list chrome yellow was shown as one of the pigments used frequently, and therefore he and his colleague were bound to see whether it faded in the light. Yellow chrome by itself did not fade in the light. He did not think nowadays anybody would put chrome yellow in his colour-box, because certain actions took place with chrome yellow when other colours were mixed with it. Personally he should never think of using chrome yellow. Then a comment had been made on the fact that he had not mentioned light red. One could put light red and Venetian red one on the other, and it did not make the slightest difference; they were exactly the same. He had tried both, and neither had faded. With regard to Chinese white, he was not sure that pure water-colour artists ever used Chinese white, and therefore he had not paid any attention to it. It had been found, however, in the experiments that the Chinese white as supplied did not blacken, but he would rather not pledge himself about Chinese white, as water-colour artists seldom used it. With regard to the question whether madders faded when mixed with blacks, it was rather fatal to mix those delicate colours with black. If, for instance, madder purple was mixed with black, a change must be expected. There was something peculiar about the mixture of black with such colours that required a little more investigation. A very sensible question had been asked about arc light and ozone. When an arc light was used a lot of ozone came off. The action would take place with the arc light, but it would not occur as quickly as with the ozone tube, where the ozone was all conducted to the pigment. Those who had an arc light could very easily experiment for themselves. It might be taken that an arc light had very much the same action as sunlight. He had been delighted to see Mr. Lovibond present. That gentleman's tintometer for measuring delicate shades was well known, and science generally was grateful for it. He thought the burden of Mr. Harrison's remarks was that vermilion was classed as a permanent colour, and that at a temperature of 50° C. (122° F.) it would turn brown. That was a pretty high temperature, and probably Mr. Harrison was right, but he (the author) thought the temperature at which vermilion had to live was rarely above 100° F. He had not found himself that vermilion had turned black. In the original report it was shown that vermilion had turned black, to a certain extent; but when the blackness was taken off by scraping, the vermilion was found intact underneath. He had been very interested to hear how the Chairman had been taught in three colours. That was an ideal method, but there were some colours which could never be obtained with three colours; the tint would be obtained, but not the proper depth.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his interesting paper.

THE OCCURRENCE OF VOLCANIC ASH ON THE GREAT PLAINS OF NORTH AMERICA.

By Chas. N. Gould, Ph.D.

Volcanic ash (pumicite) occurs in large quantities on many parts of the great plains of North America. It has been found most abundantly in western Nebraska, Kansas, Oklahoma, and Texas, and in eastern Colorado and New Mexico.

This material, which is ordinarily white or cream-coloured, usually occurs as rather loosely-consolidated beds, varying in thickness from a few inches up to 10 ft., and occupying an area sometimes of several acres. These beds are lens-shaped, and are usually found interstratified between shales, clays, and sandstones of the Tertiary age, which latter deposits occupy the greater portion of the parts of the States mentioned.

The origin of this material is not absolutely known, but it is believed to have come from volcanoes, presumably of the Tertiary age, the remnants of which are in evidence at points west of the present deposits in certain parts of New Mexico and Colorado. Theoretically it is assumed that at the time of eruption this volcanic ash was carried by strong western winds, and spread out over the surface of the country. Afterwards this surface was submerged, and the deposits were buried under the superimposed sediments. Erosion is now uncovering these various beds.

Within the past few years certain deposits have come to light in eastern Oklahoma, at a distance of at least 400 miles from the nearest known Tertiary volcanoes. The age of these deposits cannot be accurately determined. They are known to be post-Pennsylvanian in age — that is to say, they now occupy a position on rocks of Middle-Carboniferous age. The exact time of their deposition may have been anywhere later than late Paleozoic.

An analysis of this volcanic ash indicates that the material is largely silica, varying from 95 to 99 per cent. SiO_2. A microscopic examination shows that the particles are glassy, transparent, irregular in shape, and consist of minute fragments and spicules.

This material has been mined locally, and is

used chiefly in the preparation of various scouring compounds. It is mixed with animal and vegetable fats and oils, and sold under a variety of trade names. Immense deposits of the material are available, but heretofore only a very small amount of it has been utilised.

SOCIAL AND ECONOMIC PROGRESS OF THE NEGRO FARMER IN THE UNITED STATES.

On January 1st, 1863, Abraham Lincoln proclaimed the abolition of slavery in the United States; other laws which followed between that date and 1865 completed the liberation of the slaves by giving them full rights of citizenship. Almost half a century, therefore, has passed since the negroes were admitted to form part of the civil and economic life of the great American nation—half a century in which they have made enormous progress.

The *Monthly Bulletin of Economic and Social Intelligence* devotes an article to the study of the progress of the negroes in agriculture. Since the majority of the negroes (2,143,154) are employed in agriculture, the article in question covers the most interesting part of the story of the progress of the race.

Before 1861 the negro slaves in the United States were confined to the South, and furnished the whole of the labour required on the plantations for the cultivation of cotton, sugar, rice, and indigo. They were the type of labourer best adapted to work under the system which prevailed at that time—hard-working, obedient, inured to fatigue. It was but natural, therefore, that the Southern States should oppose the abolition of slavery; and their opposition yielded only after their unsuccessful appeal to arms in the War of Secession. Even after the war discontent against the laws freeing the slaves was manifested in different forms, and a period of unrest and internal disorder followed the year 1865.

From 1865 to 1872 there was a very large emigration of negro workers from the country into the towns. The movement did not cease when normal conditions were re-established in the South, though it is now in the nature of a natural current towards the towns, about equal in degree to the parallel movement on the part of the white population, and due to analogous causes. At the present time, out of a total of 9,800,000 negroes, 8,700,000 are in the Southern States.

But while the number of negro agricultural labourers has been diminishing relatively, by comparison both with the numbers of white labourers and with the number of negroes employed in other occupations, the opposite is true of the other classes of negroes engaged in agriculture. Relatively, the share-croppers, tenants, and proprietors are increasing.

This is a reassuring circumstance, as it shows that the tendency is for the negro to improve his position. He rises slowly and gradually from the lowest form of share tenancy, which is really only a method of hiring labour—the labourer being kept on the land by retaining, until the crop is harvested, that part of his salary which is paid in kind—up to the more developed forms of share tenancy, and finally, to tenancy with complete responsibility.

Whether we are considering the number of farms (21 per cent.) or the area cultivated (7 per cent.), the increase in the negro farmers working under the latter tenancies has notably increased in the ten years from 1900 to 1910.

But still more commendable has been the acquisition by negro cultivators of the ownership of land.

Whereas in 1861 the few free negroes living in the United States owned but an insignificant amount of the total farm land, the census of 1900 gives the value of the property owned by negro cultivators as about 230,000,000 dollars, and the following census in 1910 places the value of the agricultural property (land and buildings) belonging to coloured farmers in the Southern States alone at 272,900,000 dollars, as against 106,600,000 dollars in 1900.

This result must be considered remarkable when it is remembered that fifty years ago the negroes possessed nothing—neither inherited land nor the money to acquire land for themselves. To reach the point at which they are to-day, the negro farmers have had to exhibit powers of working and of saving which might in some cases with justice be called heroic.

The various agricultural associations which exist, uniting as they do the scattered efforts of the worthiest representatives of the race, have contributed much to the progress of the negro in agriculture. Equally admirable has been the work of the Federal Government and of the separate States, of Universities, of religious institutions and of individual patriots and philanthropists.

With the help of all these forces the negro farmer is making rapid progress, not only economically, but intellectually and socially as well. He is becoming a better farmer and a more valuable citizen.

THE COMMERCE AND INDUSTRIES OF MADEIRA.

Since the inauguration of winter cruises to the Mediterranean the island of Madeira has developed rapidly, and its industries are flourishing. The island lies off the coast of Morocco, 550 miles south-west of Lisbon, and 640 miles from Gibraltar, and is about 40 miles long from east to west and 15 miles wide from north to south. It is of volcanic origin, and its mountains attain an altitude of 6,000 ft. About half the total area of 175,000 acres is under cultivation, and of a population of 170,000 two-thirds are engaged in agriculture. With a mean annual temperature of 66° F. Madeira is a well-known winter resort, with a tourist population of 3,000 during the season. Funchal, the capital, is a port of call for vessels between Europe and

North and South America, and it is estimated that the total annual transient population is about 150,000 persons, of whom 34,000 are en route to or from the United States.

The embroidery industry is the most important on the island, employing 40,000 to 50,000 persons, and having an annual output valued at £165,000. Embroideries are exported to the United Kingdom, France, Germany, and the United States, and, according to the American Consul-General at Lisbon, the latter country receives very considerable quantities of Madeira embroideries.

The annual production of Madeira wine is 12,000 pipes. Sugar-cane has supplanted the vine in many parts of the island. In 1912, 48,000 tons were used, yielding 4,200 tons of sugar, 4,000,000 quarts of treacle, and 42,000,000 quarts of alcohol. Generally the industry works with cane juice of a grade of 8° or more Baumé, and the yield of sugar is about 10 per cent. Five hundred men are employed in the sugar factories. In 1911 the Government placed a tax on alcohol, to be levied until 1918, which yields an annual revenue of £22,000.

The wicker furniture industry employs 600 persons, and the annual exports amount in value to £14,000. Inlaid woodwork gives an annual return of £2,400. The demand for furniture in these styles comes chiefly from visitors to the island.

The canned and salted fish business has seen considerable development in recent years, and now employs about 3,200 persons. Shipments are made to the United States and Northern Europe. About 4,000 skins of kids are exported to Oporto each year for use in glove manufacture.

Madeira is rich in fruits, and large quantities of bananas are exported, principally to Portugal and Continental countries generally. A special service has been organised by the Government to foster and protect fruit trees. Owing to the regular fast steamship service between Funchal and the ports of England and the Continent, it is proposed to undertake the shipment of flowers, which grow in great profusion in all parts of the island, and are in blossom the year round. The manufacture of perfumes is also under consideration.

One of the great drawbacks to the development of Madeira has been the lack of transportation facilities, but the local government has planned many improvements. A railway runs from Funchal 3,000 ft. up the mountain to a large hotel. Between Funchal on the south and Porto Moniz on the north a road, 20 ft. wide, is under construction, much of it cut out of the solid rock. An appropriation of £150,000 has been made for opening public highways and improving the drainage system. Ox-carts for passengers and goods are giving way to motor transport. There are sixty-five motor-cars in regular service, although the only available thoroughfares are the streets of Funchal, and a road running to suburbs on the coast about seven miles in each direction. Since the streets are paved with pebbles and cobblestones, motor-cars need to be strongly constructed.

ARTS AND CRAFTS.

Metalwork and Jewellery.—Messrs. Ramsden and Carr's annual show of metal and silversmiths' work has come to be an event to which many people look forward with pleasurable anticipation. It was, therefore, satisfactory to find that the absence of one of the partners with his regiment did not prevent the exhibition from being held. The effects of the war had not, of course, as yet had time to tell upon the work shown; orders for large objects, now sufficiently advanced to be exhibited, must have been placed well before August, and it had been possible to arrange a very representative collection of work. This year the large-scale metalwork occupied a conspicuous place. Three altar crosses were on view, two in brass and one in gunmetal, as well as a crozier and several sets of altar candlesticks - all of them very well worth notice. The more important silver work included a covered standing salt for the Worshipful Company of Merchant Taylors, remarkable for its wealth of symbolism, and a pair of candlesticks in wrought and repoussé silver, with briar rose decorations, which were thoroughly fresh in design and conception. The drawing for the chalice and paten for the Chapel of Whitelands College also promises well. A set of jewels comprising the St. Christopher and the Tristan and Isolde rings the one in gold and platinum, the other in chiselled gold alone -the St. George pendant and the bracelet in hand-wrought platinum and blue moonstones were, however, in some respects the most remarkable exhibits. The small objects, it is true, allow less scope than the larger ones for the display of those virile qualities for which Messrs. Ramsden and Carr are best known, but they offer ample opportunity for refined and fanciful design and workmanship We have at present many artist-jewellers doing good work along the lines of the tasteful combination of stones and simple wirework, but their attempts at the introduction of the figure or at chiselled work of any kind, though occasionally suggestive, are almost invariably rather heavy. They all seem to assume an inordinately large and imposing person to wear the trinkets and to carry them off. Messrs. Ramsden and Carr's figure work, on the other hand, is eminently fit for its purpose, besides being artistically conceived, and it may, therefore, be looked upon as more or less of a triumph.

Fans.—The Loan Collection on view at Messrs. Colnaghi and Obach's, in aid of the Queen's Work for Women Fund and the Australian Contingent Association, is at least as interesting from the point of view of the artistic craftsman and the lover of decorative painting as from that of the painter. It includes not only a very good and representative assemblage of fans and drawings on silk by Charles Conder, which show to the best advantage that artist's delicate colour and tender fancy, but also an extremely interesting collection of eighteenth and nineteenth century

fans lent by Mrs. Frank Gibson. The fans shown are English, French and Spanish (there is one Italian fan mount), and it must be admitted that the French work has, as a rule, a lightness and refinement which is lacking in English specimens. That defect is, however, rather characteristic of the smaller English work of the period. When seen by itself it often looks very satisfactory, but in juxtaposition to French painting or furniture it generally presents a rather clumsy appearance.

The thought which the collection suggests is that English craftworkers have been neglecting what really is an opportunity. Several artists of repute have painted fans, but the artist craftsman has, with very few exceptions, left them severely alone. And yet, as the beautiful French and Spanish work on view at Messrs. Colnaghi's indicates, the fan offers him a splendid opportunity. The wood-carver has a chance to try his hand at simply carved mounts, but above all the needlewoman is afforded an excellent opening for the display of her taste and her capacity for simple design. Elaborate embroidery is, it is true, rather out of place on a fan which has to be repeatedly opened and shut. Beautiful lace, enchanting as it may look, is hardly effective from a practical point of view. But the old workers have shown us how altogether satisfactory a design of sparingly used spangles can be, and simple needlework arranged so as to take advantage of the rounded top of the open fan and to balance it by insistence on the radiating lines of the mount would have a very charming effect. Cheap Japanese fans have of course many attractions; it would be quite impossible to compete with them, and they answer many purposes quite admirably. Hand-painted fans by really first-rate artists are beautiful, but quite beyond the purse of the ordinary buyer There ought to be an opening for something between the two extremes of price, and any needlewoman with some knowledge of design who visits the present exhibition should come away with some idea of how to plan a fan which would be attractive and yet fairly simple in character.

Christmas and the Artistic Crafts.—Christmas is generally the harvest time of the small artist craftsman, and it is satisfactory to find that although some of the opportunities which are usually provided at this time of year for the disposal of his goods are lacking, other means of showing his work have been found. Various sales have been held, and, further, British hand-woven goods were shown at one of the London shops. They made a very good display in the windows. though the people who had charge of the selling might, with advantage, have been taught a little more about the wares, and have been brought to a better understanding of the reason why hand-woven goods are so much more expensive than those which they are normally accustomed to handle. Some of the exhibitors, for their part, would probably have sold better had they taken the pains to try to put themselves into the position of people buying Christmas presents. The demand in London at this season of the year is always mainly for small and comparatively inexpensive objects suitable for presents. It is only natural that in a war year there should be a contraction rather than an expansion of the market for large and comparatively costly work In any case, the experience of those who are trying to sell craftwork this season seems to be that while there is, all things considered, a very fair demand for little inexpensive objects, no one wants to buy large and expensive things.

It is always difficult to hit the happy mean between producing fine things which will not sell and descending to the making of knick-knacks, fit, perhaps, for a bazaar, but not worthy to be considered seriously from the point of view of either art or craftsmanship. It is to be hoped that our craft workers will not despair of solving the problem.

Artistic Toys.—A certain number of more or less unemployed artists and craftwomen seem to be drifting into the toymaking industry, which is now being so vigorously prosecuted. The whole trade is, of course, at a highly experimental stage, but if it can be made sufficiently successful to employ permanently, at proper wages, a fair number of people with some artistic training and taste, a very excellent work will have been accomplished. It is really remarkable, when one comes to think of it, that while in recent years so much has been done to improve the artistic quality of children's picture-books, we have been content to allow so many of their best beloved toys to be so hopelessly ugly. The trouble is probably due to the prevailing passion for cheapness. German toys were cheap, and while they were available it was no use trying to introduce a more expensive type of thing, however much better it might be. Of course, some of the all-British toys being made are in no sense artistic; and there are toys much beloved of children, such as penny whistles and mouth-organs, to say nothing of guns and cannons, which do not lend themselves to artistic treatment. Again, though it may be heresy to say so, the average small child has not very strong predilections in the direction of art, and generally prefers a frankly hideous gollywog to the most highly impressionistic, or even futurist, spook. On the other hand, one cannot but feel that if only Noah's Ark animals and the like could be made in some quantity, and at a reasonable price, on the lines of the really beautiful beasts lately shown in Bond Street and elsewhere, the children who played with them would love them, and at the same time would get some idea of what the animals really looked like, which is far from being conveyed by the four-legged objects enclosed in the ordinary Noah's Ark. With regard to the people, it might be rather sad to have to give up discussing which was Mr. and which Mrs. Noah; but, after all, that

question is really more often raised in the first instance by the grown-ups than by the children themselves. We are beginning to see in the various shops this year a certain number of toys, not all of them very expensive, which show that those who have had a hand in their making have some artistic sense, and are at the same time keeping before them the child's point of view. It is to be hoped that the efforts directed towards building up a British toy industry will continue to include a consideration of the artistic side of the matter, and that when the trade is fully grown it will not offer us copies of German productions, but will put upon the market better animals, farms, carts, shops, etc., than those which have been imported. At present, some of the superior toys are being hand finished by trained carvers or painters, a proceeding which opens up almost infinite possibilities for the future.

CORRESPONDENCE.

HIDES AND TANNIN EXTRACT OF QUEBRACHO.

It might be useful at the present juncture to point out the large quantity of hides and tannin extract of quebracho which is usually exported from this country to Germany.

Owing to the war many of the tannin factories are closed, and the price of hides in the camps has fallen to 0.25 cents paper per kilo (twopence per pound). Great quantities of leather must be used in the war, and English tanners might well take the opportunity of extending their operations.

The tannin of quebracho is contained in the wood, and one ton of timber gives one-third ton of tannin extract. An acacia called cebil contains a superior tannin in its bark, but there is no commercial development of this product on a large scale.

Quebracho tannin extract costs about £15 per ton to produce at the works. The supply is unlimited.

Requests for further information may be addressed to me at the Royal Colonial Institute, Northumberland Avenue, London, where I shall call next month.

THE TRAINING OF INDUSTRIAL CHEMISTS.

Mr. Dibdin's letter on this subject raises a question that was not dealt with in the papers of Sir William Tilden and Dr. Ormandy, and which has an important bearing upon the future of chemical industries in Britain.

Manufacturers are in some cases, no doubt, ignorant of the scientific principles which govern their processes, but on the other hand there are many who fully appreciate the value of constant research, but experience a difficulty in finding men capable of carrying it out. It is not always possible to distinguish between "pure" and "applied" chemistry; but where our colleges usually fail is in not impressing upon the students the application to industrial processes of the principles taught. As a result, as Mr. Dibdin points out, the students of such colleges require training afresh before they are capable of filling situations in industrial life. Sir Walter Noel Hartley, who was a pioneer in the teaching of industrial chemistry, used to preface his lectures on this subject with a remark that deserves the widest recognition: "There is almost an infinite difference between a process carried out in a beaker in the laboratory and on the large scale for commercial purposes." The truth of this dictum does not seem to be realised by most of our teachers, and in consequence the type of student turned out is unsuitable for industrial requirements. As an example, I have frequently met students thoroughly conversant with all the laboratory methods of producing low temperatures, but who did not understand the working of a commercial refrigerating machine, and could not recognise one when they saw it. The text-books used are in most cases solely devoted to laboratory methods, although occasionally a brief mention may be made of the outline principles of a large-scale operation, as a sort of addendum to the laboratory process. It is largely owing to this omission to teach industrial chemistry that the manufacturers in this country have little confidence in the colleges or in the class of men who have been trained therein.

Turning to the question of research, the same ignoring of industrial problems may be observed. All research is of the highest value, as extending the bounds of our knowledge, and should therefore be fostered. The vast majority of the chemical researches carried out at our colleges, however, have no commercial significance, and do not attract either the manufacturer or the financier. Often, moreover, a successful laboratory investigator may fail to succeed in solving industrial problems, where machinery takes the place of the spatula, and the large furnace that of the Bunsen burner. Success in industrial research involves far more than a knowledge of chemical principles; it entails an intimate acquaintance with machinery of various kinds, the economic working of furnaces, temperature control, and many other matters of which the student who has worked only for a degree has no knowledge. Research of this character, when not conducted by a member of the works staff, is referred to the consulting chemist, who, not usually being free to publish the results of his investigations, gets little or no credit either from the public or in scientific circles. The only sources from which the manufacturer can obtain chemists who are immediately of use to him for research purposes are the laboratories of the

consulting chemists, and from the very few colleges in which a training in industrial chemistry is given preference to preparation for a degree. My own experience confirms that of Mr. Dibdin, that there is no difficulty in placing suitably-trained students in satisfactory positions; indeed, the demand is often greater than the supply.

If we are to have that co-ordination between the teacher and the manufacturer that exists in Germany—to the great advantage of both—the teaching of chemistry must not, as at present, be mainly confined to the cloister. We must either introduce courses of instruction in industrial chemistry into our existing colleges and universities, conducted by men of experience, or create new institutions for the purpose. We must look upon industrial knowledge as an educational asset equal in importance to book knowledge, which at present we do not. So long, however, as educational authorities continue to regard the possession of a degree as the only criterion of ability, and form their staffs almost exclusively of men who have had no industrial experience, they will never give that effective assistance to the manufacturer which will enable us to hold our own in the sphere of chemical industry.

CHAS. R. DARLING.

GENERAL NOTES.

PANAMA CANAL TRAFFIC.—From an article in the *Canal Record*, which publishes an interesting analysis of the traffic of the Panama Canal, it appears that during the first three months of its commercial operation, from August 15th to November 15th, the cargo transported through the Canal has amounted to 1,079,521 tons. During the fiscal year ending June 30th, 1914, the Panama railroad carried 643,178 tons of through freight between the two seaboards, and in the preceding year 594,040 tons. From this it is seen that between six and seven times as much cargo is passing over the Isthmus now as passed over this route when goods were transhipped by rail. In other words, the traffic through the Canal in the first quarter-year of its operation has been equal to about 88 per cent. of the through traffic over the Isthmus during the preceding two years.

THE ANGORA GOAT.—During the last few years great attention has been directed to the breeding of Angora goats in the United States of America. The value of the 1909 clip of mohair was $901,597, which is nearly four times the value of the clip of 1899. The number of fleeces increased during this period from 454,932 to 1,682,912. The weight of fleece for American Angoras varies from 2 to 12 lbs. The fleece of a one-year-old goat weighs about 2½ lbs. The total weight of fleeces produced in the United States in 1913 amounted to nearly 5,000,000 lbs. Besides this considerable home production, the United States import about 2,000,000 lbs. of mohair, which is on the average superior in quality to the American produce. The best conditions for goat-breeding exist in the north-western States, where there is abundance of brush, and where the goats contribute greatly to the control of forest fires by clearing brush lands.

POTASH SALT SUPPLIES.—Attention is drawn in the annual report of the Royal Agricultural Society of England to the cutting off of the supplies of kainit and other potash salts caused by the outbreak of war. These salts were obtainable only from the Stassfurt and other mines of Northern Prussia. By this great difficulties will be imposed alike on the farmer who needs potash on his land and on the manufacturers of artificial compound manures. At present there is no regular supply to be obtained elsewhere, though it may be found possible to use the insoluble felspars and other minerals as a source of potash. From India and elsewhere supplies, to a limited extent, of nitrate of potash (nitre) may also be available at enhanced prices. Possibly, too, the dearth of potash salts may lead to the revival of the practice of kelp (seaweed) burning; but these and other remedies suggested can only be looked upon as very partial means of supplying the need. Meantime it is well to remember that Peruvian and other guanos frequently contain notable amounts of potash, as does also farmyard manure.

THE NEW ZEALAND WOOL AND FROZEN MEAT INDUSTRIES.—Wool is the most important article of export from New Zealand, and its production is growing steadily. Great progress has been made in the last decade in improving the quality of the sheep, and breeding for greater quantity as well as better quality of fleece is now being made the subject of careful study. It is estimated that the scientific farmer gets an average of fully 30 per cent. more wool from each sheep than was obtained ten years ago with a better quality of product. The commercial prosperity of New Zealand commenced with the advent of the freezing chamber in 1882, enabling the sheep farmer to utilise the carcass of the animal as well as the fleece. Frozen meat ranks second among the exports of New Zealand produce. The growth of the industry is illustrated by the fact that the exports in 1882 amounted to 1,707,328 lbs., while in 1910 they were 291,200,000 lbs. Given a demand at remunerative prices, this industry is capable of indefinite expansion, for there are yet large areas of suitable land that only need to be furnished with transportation facilities to be rendered available for settlement.

AN EARLY SUBMARINE BOAT.—In view of the important part now played in naval warfare by submarine vessels, it is interesting to note that fifty-five years ago (January 14th, 1859) the *Journal* contained an account of an American invention of which it was claimed that "it would make such a change in the mode of carrying on a naval war as would put steamers out of the question, and render of no avail the tremendous forts of

Kronstadt and Cherbourg ... It is nothing less than a submarine boat, made only for working under water, in form much resembling the shape of a porpoise, but capable of being made large enough to contain eight, ten, or even fifteen men, if necessary, with a proportionate quantity of explosives." The patentee stated that he, with others, had submerged the boat in Lake Michigan, and remained under water for four hours, without any air tubes or other communications, and propelled the boat in and near the bottom of the lake for several miles at the rate of about three miles an hour. He claimed that he could convey powder torpedoes of 100 lbs. weight in his boat, and when under an enemy ship pass them out of the side of his boat through his patent hatch, fasten them to the ship's bottom, and fire them. One of the most remarkable points about the description is that he appears to have used a periscope. "He can enter an enemy's harbour under water and make surveys, only showing above the surface a sight tube no more than one half-inch in diameter, and retire still under water, and proceed out to sea and make his report to the commander of a fleet or ship." The account in the *Journal* says nothing of the means proposed for supplying the crew with air, nor is any description given of the means of propulsion

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 20.—J. A. Hunter, "The Textile Industries of Great Britain and of Germany." Lord Rotherham, President of the Textile Institute, will preside.

January 27.—Hon. John Collier, R.O.I., "Portrait Painting." Lord Sanderson, G.C.B., K.C.M.G., will preside.

February 3.—Octavius Charles Beale, Chairman of the Australian Manufacturers' Association, "Imperial Industrial Development after the War."

February 10.—F. Vincent Brooks, "British Lithography in 1915."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 21.—Henry John Elwes, F.R.S., "Nepal."

February 11.—Captain Sir George Duff Dunbar, Bart., I.A., "Tribes of the Brahmaputra Valley."

March 18.—Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 26.—Major E. H. M. Leggett, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda."

February 2.—Edward R. Davson, "Colonial Sugar Development."

Dates to be hereafter announced:—

Thomas Worthington, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. Thorne Baker, "The Industrial Uses of Radium."

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. Hulme, "Patent Law."

H. M. Thornton, "The Industrial Uses of Coal Gas."

D. Y. Cameron, A.R.A., R.E., "Etching."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

William Poel, "Shakespeare's Profession."

Arthur Wilcock, "Designing for Textiles."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

April 15, May 13.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March, 2, 30, May 4.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Dr. F. Mollwo Perkin, F.I.C., F.C.S., "Oils, their Production and Manufacture." Three Lectures.

January 18, 25, February 1.

M. H. Baillie Scott, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Fothergill Lectures.

Monday evenings, at 8 o'clock:—

Professor Vivian B. Lewes, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

February 15, 22, March 1.

Juvenile Lectures.

Wednesday afternoons, at 5 o'clock:—

H. Plunket Greene, "How to Sing a Song. Two lectures, with vocal illustrations.

January 6, 13.

Journal of the Royal Society of Arts.

No. 3,240. VOL. LXIII.

FRIDAY, DECEMBER 25, 1914.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

JUVENILE LECTURES.

The usual short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, January 6th and 13th, 1915, at 5 p.m., by Mr. H. Plunket Greene, on "How to Sing a Song."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

Most of these have now been issued, but some still remain, which will be issued to Fellows who apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE HISTORY AND PRACTICE OF THE ART OF PRINTING.

By R. A. Peddie,

Librarian, St. Bride Foundation Typographical Library.

Lecture I.—Delivered November 23rd, 1914.

Printing with moveable types was invented either in Holland or Germany about the year 1440. The name of the inventor and the place of the invention are two of the most hotly contested questions in history. Gutenberg at Mainz, Coster at Haarlem, Waldfoghel at Avignon, Castaldi at Feltre—all these are mentioned as claimants. The value of their respective pretensions has been summed up by a well-known authority in the words: "Holland has books but no documents, France has documents but no books, Italy has neither books nor documents, while Germany has both books and documents." There exist books certainly printed in Holland which are held by some to be earlier than 1454, which is the first printed date of the Mainz press. They are attributed to the press of Laurens Janszoon Coster of Haarlem, but this is not supported by any direct evidence. As to the Avignon claim, this rests upon some documents in the legal archives of the town. Waldfoghel, who was a goldsmith, was in the possession of a method of artificial writing which, by the description given, must have been printing. No work done by him or by his method has been identified.

The claim of Castaldi, of Feltre, appears to rest upon very shallow foundations, and, in fact, it is difficult to see anything but tradition in the story. When we turn to Mainz we are on more solid ground. From the first Mainz press —it is difficult to associate John Gutenberg definitely with it—a broadside Indulgence was issued with the printed date of 1454. Through the haze of tradition, theory and speculation, this Indulgence emerges as a definite fact, and from this date begins the real history of printing with moveable type. From what we know of the operations of typefounding to-day we can see that it must have taken many years of experiment and of failure to enable the printer of the 1454 Indulgence to arrive at the final solution of the problem. From the press of Mainz also was produced the first Latin Bible, originally known as the Mazarine Bible, afterwards described as the Gutenberg Bible, and now called by all good doubting bibliographers the forty-two line Bible, which title commits no one. This Bible was printed before August, 1456, as a copy in the Bibliothèque Nationale

has a rubricator's date of that year. In 1457 appeared the Mainz Psalter, the first book to bear the name of its printer, the name of the place where it was printed, and the date of its production. To add to this, it contained the first attempts at colour printing and the first ornamental initials. The printers were Johann Fust and Peter Schöffer, and this Psalter, together with the other books from their press, showed a great advance from the work of the two first presses in Mainz.

The work of these pioneer printers must have been much hampered by the poverty of their implements. There is little doubt that the earliest press used was a simple linen-press, and a small one at that. The ink was an invention, if not in itself, in its application. With these poor instruments, and with type that must without doubt have been irregular and badly cast, the pioneers of the printing art produced the magnificent works which remained, perhaps unequalled, and certainly not surpassed, for many years.

From the Mainz press, with its colour-printed initials, we pass to Strassburg. Here as early as 1460, and perhaps two years earlier, Johann Mentelin was printing and using a type which began to show the first modification towards the round or Roman type. Everything up to this time had been printed in the type which is known generically as the Gothic or Black Letter type. About the year 1464 a press was established at Strassburg which used a definite Roman type. The printer, formerly known as the "R" printer, owing to the curious form of the capital R in the fount of type he used, and whose books were originally confused with those of Mentelin, is now identified as Adolph Rusch, the son-in-law of Mentelin. The first Roman type, therefore, is found in Germany, although we have to look to Italy for its later development. The next press to be mentioned as showing development in the art is that of Albrecht Pfister, of Bamberg. Pfister is a mysterious person, being connected in some way with the earliest presses in Mainz, and by some is looked upon as the printer of the thirty-six line Bible, which by most bibliographers is attributed to the printer of the 1454 Indulgence. The interesting point about Pfister is that seven out of the nine books from his press are illustrated with woodcuts, and form the first attempt at book illustration. None of them can be placed later than 1462. No more illustrated books occur until about 1470.

The next important event is the establishment of printing in Italy. Sweynheym and Pannartz, two German craftsmen, started work in Subiaco near Rome in 1465. They used a type which was not Gothic and not quite Roman, and is generally described as Semi-Roman. It was not based on the same style of writing as the first German Roman, as will be seen when the two are compared. Two years later, in 1467, when these printers moved to Rome, their type became still more Roman in character; but it was not until 1471 that the new character, which was really the older form of letter (this is recognised by the Germans, who to this day call it Antiqua), reached its highest point, in the type used by Nicolas Jensen, a Frenchman, who printed at Venice. This type, perfect in outline and balance, has held its artistic supremacy to the present day. The Roman type failed, however, in its competition with the Gothic, which held the field all over Europe during the fifteenth century.

Up to 1465 the Gothic and the Roman were the only type-faces in use. In that year Greek type was used by Sweynheym and Pannartz at Subiaco, and by Fust and Schöffer at Mainz. Previously a space had been left where a Greek quotation was required, and it had been written in by hand, or in some cases stamped in. The first book to contain a full Greek text was printed by Ferrandus at Brescia about 1473. It was the "Batrachomuomachia" of Homer, and the book also contained a Latin translation of the work. The development of Greek printing was rapid in Italy, but slow in the other countries of Europe.

Printing began in Switzerland about 1468 at Basel, and in 1470 in France at Paris. It is strange that Paris was so late introducing the printing press, as there is no doubt that specimens of the art had been seen there in 1466, and it is believed that Jensen was sent by Charles VII. to learn the new art as early as 1458. On his return to Paris, finding his patron, the king, dead, and encountering considerable opposition from the scribes and copyists, he went to Italy and ultimately established his press at Venice. The first Paris press was established under the patronage and by the exertions of professors of the University of Paris, and the press itself was set up within the precincts. The printers, of course, were Germans, and their work was largely reprints of classical texts. The Roman type used by these printers was of a very high artistic character, Mr. Gordon Duff, in fact, going so far as to say that it far surpasses Jensen's in beauty.

By 1473 printing was definitely established in the Low Countries, both Utrecht and Alost producing dated books in that year. In 1475 occurs the first use of Hebrew type. Piove di Sacco and Reggio di Calabria in Italy, and Esslingen in Germany, were the towns where it was first used. Many Hebrew presses were set up in Italy during the last quarter of the fifteenth century, and several in Spain and Portugal.

In 1475 the art reached Austria, and in the same year Spain. The first book printed in England was issued from the press of William Caxton in 1477. The false date 1468 appears in an Oxford edition of Rufinus on Jerome's exposition of the symbols of the Apostles. This date has given rise to a considerable amount of controversy. Richard Atkyns in 1664 alleged that this book was printed by Frederick Corsellis, a workman from the press of Haarlem, who was bribed to come to England by order of Henry VI. This story was based on a manuscript alleged to be in the Library at Lambeth Palace. No one, however, has seen that manuscript from Atkyns' time to the present day, and as it is certain that the book dated 1468 was printed in 1478 by the first Oxford printer, I think it may be taken that the existence of the said manuscript is very doubtful. However, the king (Charles II.) believed Atkyns' story and gave him the patent for law-book printing. The press in England was not responsible for any great advance in the art—in fact, English printing of the fifteenth century was of a comparatively low order.

About 1481 or 1482 music is found printed with type. In 1473 a few notes were printed by C. Fyner at Esslingen. The principal use of music was in service books, and it was always printed in two impressions up to the end of the fifteenth century. The notes are generally in black and the stave lines in red. The earlier printers either left a blank space for the rubricator to write in the music, as in the 1457 Psalter, or in a few cases printed in the stave lines, leaving the notes to be added later by hand.

A further addition to the resources of the art was the cutting of Slavonic type, which is found in at least two varieties in Cracow in 1491 and at Cettinje, in Montenegro, before the close of the century. A Secretary type following closely the French law hand is found used at Paris and Rouen in the last decade of the century. A Rouen book printed for Richard Pynson, of London (Statham's Abridgment) is a good specimen of this type.

During the last few years of the century printing presses were established in Portugal, Denmark, Sweden, and Montenegro.

We have a picture of the printing press as improved by the close of the century in a "Dance of Death," printed at Lyons in 1499. A considerable change is seen from the plain screw-press of the earliest printers. It has assumed the familiar form of the wooden hand-press known to all. There is certainly a tympan. As to the frisket, it is distinctly probable that this valuable addition to the press was the invention of some one in the office of Schöffer at Mainz. It is most likely that the diminution of the number of pinholes in the sheet which occurs in the very early seventies is due to this addition to the press.

At the close of the fifteenth century the printer had almost emerged from the experimental stage. The press had assumed the form it was to hold with very slight alteration for 300 years. Books could be printed in Roman, and many varieties of Gothic types, in Hebrew, Greek or Slavonic letters, and music type (in two printings) was constantly used. Coloured inks were known, although very sparingly used. The technique of book-making had almost reached its height. The early books were without titlepages, tables of contents, pagination, imprint, signatures and illustrations. By the year 1500 all these had been introduced, and if they were not always used it was not because they were not known.

The Sixteenth Century.

With the opening of the sixteenth century the art enters upon a period of steady progress. It is true no great inventions either of machinery or methods were introduced, but the increase in the number of works issuing from the press was steady throughout the century.

The most noticeable change is the reduction in the size of books generally, and this occurred quite early in the century. As books became more popular and cheaper they naturally became smaller. The pocket volume, rare almost to non-existence in the fifteenth century, was almost common in the sixteenth. The small octavos and quartos were well in the majority. Even the folios were less unwieldy, and the enormous volumes of the past were almost unknown by the end of the first decade.

During this century it is remarkable to notice the enormous spread of the press as well as its activity just referred to. During the years 1501–1520 no less than twenty towns in Germany set up presses for the first time. In Italy,

during the whole century, no less than 100 towns set up presses. In England the progress was not so apparent. Only twelve towns set up presses during the century, and most of these attempts expired before its close.

The struggle between the Roman and Gothic types was resumed early in the sixteenth century, and a third competitor entered the lists in the shape of Italic. It was cut for Aldus at Venice, it is said, from the designs of Francia and modelled upon the handwriting of Petrarch. Aldus obtained a privilege for ten years for the sole use of this type-face, and it was first used in the Virgil of 1501. The success of the Aldine Italic at once produced imitators. Forged editions were issued at Lyons, and printers elsewhere produced varieties of the type. As a result of the struggle between the Roman and the Gothic, the Roman began to gain ground in the Latin countries, while Gothic still remained supreme in those of Germanic origin. There began in 1509 that semi-scientific discussion of the proportions of print letters by Paccioli which was carried on by Dürer, Geoffroy Tory, and later by Moxon, which has lasted until our own day, and has produced such little real results. The real problem is to design a fount of type in such a way that whatever combination of letters is arranged no single letter will stand out from the rest. This test should be applied to any type which is put forward as an artistic triumph. Whether to these investigations should be attributed the cutting of some excellent Roman types in France is uncertain, but it is sufficient to say that such types were cut and used for many years. Roman type was introduced into England in the early years of the sixteenth century and used first by Richard Pynson.

There were also cut, during the century, founts of Arabic, Syriac, Armenian, Ethiopic, Anglo-Saxon, Irish and music types. The only one of these which needs a word of explanation is the music type. In the fifteenth century music had been printed in two workings, the notes and stave at different impressions. The new type was of a different character. Each note was cast together with the piece of stave that belonged to it, so that the stave line appeared to a close observer to be broken into as many pieces as there were notes. This system was hardly ever used (if at all) for printing the Plain chant or liturgical music, for which the old method of two printings was retained.

One extraordinary variety of Gothic type may be specially mentioned. It occurs in "Theuerdank," an epic poem celebrating the Emperor Maximilian's wedding journey to Burgundy. It was probably composed in great part by Maximilian himself. Printed by Schönsperger, of Augsburg, it was published at Nuremberg in 1517. A special fount of type was cut for it by Jost Dienecker, of Antwerp, with enormous flourishes, especially to the letters "g" and "h"; for use when these letters occurred in the first or last line of the page. Many authorities believed the whole book to be cut on wood.

The use of coloured inks in the sixteenth century was very slight. It was confined almost entirely to red, used as in the previous century principally for service books. The various shades of brown and bistre were used by the chiaroscuro printers in Italy and Germany, but any real colour printing is almost unknown.

This century may be described as the golden age of the wood-cutter. In the first half especially, numbers of great artists were producing work for book ornament and illustration. Basel, Nuremberg, Florence and Lyons are the four towns that stand out as producing some of the finest work. There is little doubt that soft metal blocks were also used, and these were produced in the same way as woodcuts.

Copperplate engraving and printing had been invented in the early part of the fifteenth century, but retained its special character, only a few books being illustrated in this manner. The use of engravings during the sixteenth century in connection with letterpress printing increased to some extent, but the woodcut retained its supremacy, and only towards the end of the century do we find any effective competition. The earliest copperplate work produced in England belongs to the period about 1540.

The printing press is supposed to have been improved about the middle of the sixteenth century by a printer named Danner of Nuremberg, who is said to have introduced a metal spindle, in place of the wooden one used up to that time. It is true that some improvement must have been made to render the press more rigid, as we find the smaller type and more delicate woodcuts used at this time coming out quite sharp and clear.

In the technicalities of bookwork the printer advanced considerably during the period under discussion. The titlepage, which only appeared occasionally in the previous century, and then only in the label form (with one or two prominent exceptions), became an integral part of the book, and the colophon necessarily decreased in

importance. Woodcut initials and borders were quite common.

The sixteenth century is not only noticeable for the great expansion of the press in Europe previously referred to. It was also the period when Asia and America received and practised the art. In India (at Goa) and in Japan the Jesuit missionaries introduced the printing press, and in Mexico an offshoot from the press of Cromberger in Seville was working before 1540.

The Seventeenth Century.

With the opening of the seventeenth century a period begins in which the art of printing continues the process of degeneration from its artistic beginnings, which was seen at the end of the previous century. It is a period of great happenings in political life, of revolutions long drawn out in England and France, and these inevitably left their impress upon the craft. The pamphlet, very little used in the fifteenth century, and only making a sporadic appearance in the sixteenth century, mostly, of course, in connection with the Lutheran controversy, became one of the normal methods of publicity, and the newspaper, the genuine periodical, not the mere paper of news, made its appearance. Old and damaged type was used, and the Dutch founders, who supplied a large portion of the demand for new type, had no type designers worthy of the name in their employ. Here and there the old punches are rediscovered and founts of type cast from them, and books can be found which preserve some of the older traditions of beauty and proportion. The Roycroft Polyglot Bible is one of these books. The Roman type used in the preface is that used by John Day, the famous London printer of the sixteenth century. There is no new Roman type to which attention can be drawn during the period under discussion. To the types known before 1600 there were added Coptic and Samaritan. There was little change in the methods of printing music, although engraving was occasionally used. The number of Hebrew presses increased considerably, especially in Eastern Europe. The most important Hebrew fount cut in England was that for the London Polyglot in 1657, and this incurred considerable criticism. In Greek work this country has at least one production to be proud of in the Eton Chrysostom in eight volumes and in folio. This work, although the types were imported (or perhaps because they were imported), takes rank with the finest Greek printing. The type is similar to the Greek of the Stephanus press.

The best printing done in England during the seventeenth century was probably that in black letter. Acts of Parliament and proclamations were printed in this letter up to quite recent times, and the Old English or English Black, which had got quite away from the Fracturschrift of the Germans, and the Flamand of the Dutch, assumed characteristics of its own which rendered it quite a handsome letter.

Joseph Moxon attempted to draw up rules for the scientific design of Roman type, but they were unsuccessful, and, in fact, were more adapted to signboards than type. Moxon praised the Dutch letter, and probably imported a great deal. It may be said that there was no indigenous Roman in England during the century.

The reason for the want of enterprise in English typefounding was the restrictions imposed upon the trade. By the Star Chamber of 1637 the number of founders was limited to four, and a commission, consisting of the Archbishop of Canterbury or Bishop of London, with six others, was appointed to fill any vacancy. Free importation was the order of the day from 1640 to 1643, and from 1643 to 1662 the trade was free of restrictions. Owing to the Civil War this did not help it much, and in 1662 an Act reimposed the restrictions of the Star Chamber Decree of 1637 (cap. 27).

In France the characters cut during the previous century still held their own, and the Elzevier Bible, although printed in Holland, is a good specimen of the finest French work of the period. Towards the close of the century a new type was cut and used largely, which showed a degraded face from the fine models of the past, and formed a link between the early types and the modern effeminate French face.

Germany and Scandinavia were by this time the only countries to retain the use of the Gothic letter for ordinary printing.

There are no typefounders' specimen books known of the seventeenth century, although several founders issued specimen sheets. But several type specimen books were issued by printers, and the two best known are Fuhrman, of Nuremberg, in 1616, and the Vatican press in 1628. Some copies of the latter are on grey paper.

The literature of the practical side of the art begins in the seventeenth century.

The English typefounder and printer, Moxon, was the first to issue a complete treatise on everything connected with the art. So good

was it that at the end of the eighteenth century it was republished as an original and up-to-date treatise. Several books giving schemes of imposition were also issued.

A few words must be devoted to the earliest newspapers. The English *Mercurie* of 1588 has been proved to be a forgery, and the first English newspaper with a definite title has been identified as the *Weekly Newes* of 1622. Newspapers were issued earlier than this in Germany and Holland, the *Frankfurter Journal* and the *Nieuwe Tijdinge* of Antwerp being among the earliest. All newspapers of the Civil War period were in a small quarto, the foolscap folio size not becoming common until after the Restoration.

The press during the seventeenth century received a general overhauling and improvement at the hands of Blaeuw of Amsterdam. The exact improvements he made it is impossible to specify, as Moxon, who gives illustrations of both the new and old presses, only describes the new.

Finally, as regards the seventeenth century, it must be noted that printing was introduced into New England in 1640, and that in all countries which were comparatively free from the stricter press laws provincial presses became more and more numerous.

The Eighteenth Century.

We now come to the last 100 years of the period I am dealing with. In many respects it is the most important, as although it did not see the great inventions which were to follow so soon, yet the development of the great industrial revolution was steadily forcing the craft towards its reorganisation as a machine industry. It will be difficult to do more than mention any of the movements on the Continent, as our attention must be concentrated on the English developments.

In 1702 the first London daily paper appeared —the *Daily Courant*. There had been a few daily numbers of the *Post Boy* in the 1680's, but the *Courant* was the first genuine daily paper. From that day the daily paper has been always with us. Whether the daily paper of 200 years ago had more news than that of to-day, or whether the censorship was working overtime then as now, it is difficult to say, but the limitations of the press at that time only gave the printer two foolscap folio pages to fill, and so there was not that wild desire for copy which characterises his descendant of to-day.

Turning to type, the Dutch typefounders were still in the ascendant, and Watson, the well-known Edinburgh printer, boasted in 1713 that all his type and ornaments were Dutch. An improvement was, however, on the way. William Caslon, the reviver of English type-founding, was born in 1692, and served his apprenticeship to an engraver of gun-barrels in London. When he started in business for himself he added the engraving of bookbinders' punches to his other trade. These were seen by the printer, John Bowyer, who introduced Caslon to James, the typefounder. After studying the art, Caslon set up in business as a typefounder about 1720. His first type specimen sheet was issued in 1734, and this contains the famous Caslon Roman types which form the model for all the standard book types of to-day. They were an instantaneous success, and until quite late in the eighteenth century were the leading style. They then dropped out of sight, and later we shall see how they came to the front again.

A great rival of Caslon was John Baskerville, of Birmingham, who was typefounder and printer, and who designed his own types and printed from them. His Romans were good, but somewhat more stilted than Caslon's, and his manner of printing and hot-pressing gave them a slimness of which all people did not approve. Baskerville's great triumph was his set of Italic capitals. These are beautiful in outline and effective in combination. His first book was the Virgil of 1757. Although Baskerville made a success artistically, his types never really became popular, and after his death they were sold *en bloc* to Beaumarchais for his printing office at Kehl. Their history after their use at Kehl is misty in the extreme, and only recently it has been rumoured that they have turned up in one of the largest provincial French printing houses.

The example of Baskerville led to imitators abroad, of whom the most famous was Bodoni, of Parma. His work retained the simplicity of Baskerville without the artistic touch of the English printer. Bodoni became printer to the Grand Duke of Parma, and his specimen book shows an endless series of Romans, Italics, Greeks, all on the most magnificent scale. His Greek Homer in folio is one of the most magnificent works ever produced. But all his magnificence does not seem to impress. His paper is too white, his ink is too black (if that be possible), and his type is too scientifically correct to please.

In Scotland the Foulis press produced some fine editions from type cast by Dr. Wilson.

When we turn to France we find all the greatness (typographically speaking) of the previous centuries departed. French Roman types had degenerated greatly. An attempt was made by Didot to follow the examples of Baskerville and Bodoni, but his attempt was poor in comparison, and French types resumed their downward course. This is not to say that there were not fine books and fine specimens of printing produced in France in the eighteenth century. There were, but there was no great revival such as took place elsewhere, and then in 1789 the Revolution diverted all printing to the pamphlet and the newspaper.

The eighteenth century did not see coloured inks used freely in connection with letterpress printing, but many processes were invented and used for producing coloured prints. For the detailed history of these I must refer to my paper read before the Society in February last.

Book illustration of the eighteenth century is very mixed. Copperplate, in conjunction with type, even on the same page, is common. Woodcuts were at their lowest ebb until Thomas Bewick revived the art by adopting the graver as his tool instead of the knife, and using the end of the grain instead of the plank. By this means he obtained a delicacy of line which enabled him to give a world of detail even in the smallest vignette. His work rescued wood and placed it in a position successfully to rival copper.

A word must be said as to the spread of the press. This may almost be said to be universal. In every part of the world, by the end of the eighteenth century, the press had penetrated. Even in England the provincial press began to bear some relation to the importance of the various localities. A feeble attempt on the part of the Government in 1793 to insist on the registration of all printers did not succeed, but before the end of the century it became tolerably common for the printer's name to appear on his work. For many years it had been the exception rather than the rule, perhaps because of the rigid press laws.

And now, as to the printing press itself. We have seen it as a simple screw-press used by the earliest printers, developing within a very few years into the wooden hand-press complete with rolling bed, tympan and frisket. We notice in the earliest pictures the inking balls of the pressmen. Now at the close of the eighteenth century, 350 years after the first printer sent the first proof to press, we leave the press still wood, still with the slow motion that only allowed the quickest pressman to get 300 pulls in a working day, and still with the inking balls of the early days. To convey an idea of the method of the printer of this time I give a list of the operations necessary for making one impression:—

1. Inking the balls, or, as at present, the roller.
2. Inking the form.
3. Laying the sheet on the tympan.
4. Flying the frisket, and folding it and the tympan down on the form.
5. Running in the form under the platen.
6. Taking the impression by depressing the platen.
7. Running out the form.
8. Lifting the tympan and frisket.
9. Releasing the sheet and placing it on the bank.

It will always astonish those who examine this practical side of the history of printing that with such slow methods the great books, and still more the great newspapers of the eighteenth century could ever have been produced.

THE DAIRY INDUSTRY OF GREAT BRITAIN.*

By C. W. Walker-Tisdale, F.C.S., N.D.D.,
Member of the Council of the British Dairy-Farmers' Association.

For the last twenty years the dairy industry in Great Britain has been steadily growing in importance, and dairy farming has to a large extent taken the place of other kinds of farming.

This may be accounted for by the increased consumption of milk by the populace, which has been and still is being educated to realise the high feeding value of milk, which has become more and more part of the national everyday diet of adults as well as children.

An estimate made some time ago put it that the annual increase in the consumption of milk amounted to 5,000,000 gallons, but it is doubtful if such will continue the annual figure if the retail price of milk is unduly increased. But whilst people are learning more concerning the value of milk in their daily dietary, it is as yet difficult for the majority to realise that in proportion to its cost it is the cheapest food obtainable. Thus whilst the price of most foods has gone up recently, that of milk also has been slightly increased. An increase in the price of milk, however, is generally resented by the public, which resentment is apt to show itself in the form of a decreased consumption. People would not, however, endeavour to effect economies in their living expenses by cutting down the quantity of milk purchased if they possessed a proper knowledge of the feeding value of this food

* Reprinted from the *Monthly Bulletin of Agricultural Intelligence and Plant Diseases*, International Institute of Agriculture, Rome.

in proportion to its cost. Undoubtedly no other food can be obtained in Great Britain at as cheap a rate, taking into consideration its food value.

Now of what value is the dairy industry of Great Britain at the present time? The answer is supplied in some figures recently published by the Statistical Department of the Board of Agriculture, by which it is shown that the estimated quantity of milk produced, after allowing for the amount used for calf rearing, is 1,208,000,000 gallons per annum.

As to the manner in which this milk is dealt with, it is calculated that 70 per cent., or 850,000,000 gallons, is sold as milk, whilst the value of the dairy products respectively as sold by the farmers is—

£24,963,000 for milk,
£590,000 ,, cream,
£2,940,000 ,, butter,
and £1,400,000 ,, cheese.

These figures show very clearly the great value to the farming industry of the milk sold for consumption in the towns, whilst the total sum realised for the milk and its products is about the same as that realised for the wheat, barley and oats grown. Furthermore, it nearly reaches the sum obtained for cattle sold as meat.

It would be interesting and instructive to compare these figures with similar estimates for, say, two decades back, but unfortunately this cannot be done, such returns not being available. What has happened, however, in recent years is that dairy farming has steadily been taking the place of corn growing, and arable land has been turned into pasture to suit the altered class of farming, thus resulting in an ever-decreasing area of cultivated arable land.

Where corn growing has not been found to pay, dairy farming has generally been substituted, and it has also largely taken the place of fattening cattle—a class of farming which has not been very remunerative of recent years, owing to the large importation of foreign and colonial meat that has come into operation.

Now whilst the importation of butter and cheese from abroad largely influences the value of these commodities as produced in Great Britain, there is practically no importation of milk to affect the value of the new-milk trade. The populace of Great Britain, whilst existing and being dependent chiefly on foods imported from abroad, is fortunately able to obtain a supply of home-produced milk to meet its requirements fully. Small quantities of fresh milk are imported from countries within easy reach of the British Isles, but the quantity is negligible and the trade at present shows no prospect of developing.

Milk-selling has been described recently as the sheet-anchor of the English farmer, and certainly it has assisted him to an extraordinary extent when other systems of farming have failed. He realises that he is free from the competition created by imports from abroad that exists in the case of most other commodities, and thus is able to develop his trade without the fear of having to compete with others who can produce milk at cheaper cost. The retail price in towns varies from 1*s*. 2*d*. to 1*s*. 4*d*. per gallon. In many large towns up to within about four years ago milk was sold at 1*s*. per gallon all the year round, but it is now generally sold at 1*s*. in summer and 1*s*. 4*d*. in winter, making an average price of 1*s*. 2*d*., though in many of the large towns it does not vary from 1*s*. 4*d*. all the year round, and 1*s*. 8*d*. per gallon is charged for the best-class trade in London.

Generally speaking the wholesale price of milk throughout the country may be taken as about 7½*d*. per gallon net to the farmer throughout the year after the freight charges have been deducted. About 8½*d*. net is obtained in the winter and about 6½*d*. net in the six summer months. The cost of transport in the country generally may be taken as 1*d*. per gallon, which conveys the milk up to 100 miles. Comparatively little milk travels short distances so as to secure the ½*d*. per gallon rate which conveys it for twenty miles.

It is not the same with the butter and cheese trade, however, for these have to compete with imports from very many parts of the globe. The imports of butter into Great Britain are valued at £24,000,000 and those of cheese at £7,000,000, which totals more than the whole amount realised for milk, cream, butter and cheese produced in the country. The cost of production in most countries from which butter and cheese are received is much less, owing to cheaper land, cattle, feeding, etc.; hence the development of the milk trade in Great Britain at the expense of the manufacture of cheese and butter, as shown in the figures previously quoted.

The question arises as to what is being done to cope with the increased demand for milk and the possibility of the demand being greater than the supply. As previously mentioned, more and more arable land is being converted into pasture, which is the main requirement for dairy farming; but apart from this must be considered the number of stock capable of being carried by the total amount of land available. Farming in Great Britain is still regarded as one of the less important industries, though there are many movements on foot at the present time to make it more productive and to increase the area of land available for agricultural purposes, by bringing under cultivation soil which at present is more or less unproductive. If, however, these points are left out of consideration, and it is assumed that the present available land is carrying practically all the stock it is capable of doing, which we think is by no means the case, there is still a means of increasing milk production. This is by means of increasing the yielding capacity of the dairy cows, or, in other words devoting special attention to breeding and selecting animals for high yields of milk. A great deal of work is now being done in this direction both by individual dairy farmers and public bodies—work that ten years ago merited but little attention. If the average yield per cow, as is estimated for

Great Britain, is only some 350 to 400 gallons, then it follows that much improvement is possible. Milk records are being carried out by various county councils and dairy associations, the results of which show the quantity and quality of the milk yielded annually by each individual cow in the herd, and this information enables the farmer to retain only the cows which give satisfactory results.

In Scotland a number of dairy societies have been started and have been in operation some five or six years, with the result that milk record schemes of great value have been obtained, and much growth in this is being continued. It is found that in most herds the variation in the annual yield per cow is great, for whilst the poorest animal may give 350 gallons or less, the best may be yielding 1,000 or perhaps more. Now the cost of keeping and tending an animal yielding a large quantity of milk does not much exceed that of a poor cow; hence, if only good cows of tested capacity are kept, as much as 50 per cent more milk may be obtained from a similar number of cows.

Most dairy farmers, even men who have been engaged in the work for many years, seldom know the milk yield of each cow in their herds, and milk records have shown as wide a difference between two herds on adjoining farms as 200 gallons per cow. Thus the farmer whose herd averages 600 gallons per cow per annum may look forward, by exercising care in selecting his cattle, to increasing the yield to 800 in the course of a few years.

Numerous dairy farmers, however, do not breed their own stock, but instead buy cows which they retain for one, two or three years, and then sell them off fat to the butcher. The calves of such animals are usually also sold to the butcher, and this system of dairy farming tends to reduce the quantity of milking stock in the country, and many of the best dairy cows are thus lost. Such may be considered a very extravagant method of dairy farming, and to the farmer in this case milk records do not appeal, as he does not keep his cows a sufficient length of time and does not retain any of the progeny, even of the best ones.

The favourite breed of dairy cattle throughout the country is the Dairy Shorthorn—an animal of Shorthorn type but not of pedigree strain. A good animal of this class may be valued at from £18 to £25.

The factory system of dairying is not extensively carried on in Great Britain, but in Ireland there are a very large number of creameries, and butter-making on Danish methods is practised. In England the large centres of population require the milk for consumption, but in Ireland there are but few large towns, and their requirements of new milk are limited, allowing for an extensive manufacture of butter. Where factories exist in Great Britain they usually engage in all branches of the dairy industry, selling milk to the towns whenever possible and making cheese and butter. The former generally gives better returns than converting the milk into dairy products; hence the manufacturing periods are chiefly when milk is plentiful and the markets overloaded. Of course in many cases there are factories where cheese or butter is manufactured and milk-selling not undertaken, but these are becoming fewer and exist chiefly in the more isolated districts. The greater part of the butter and cheese produced is still made on the farms, but even this is rapidly changing, and where farmers formerly manufactured the milk at home they are commencing the sale of the milk.

A number of factories on co-operative lines are being established. Such factories, started and run by the farmers themselves, are proving a very satisfactory means of regulating the milk trade, as when there is a surplus of milk it need not be placed on the market and so lower prices, but can be converted into cheese and butter. Further, where the milk is manufactured at a factory it is possible to produce an article of more uniform quality than is the case at individual farms, and the smaller dairy farmers are thus enabled to obtain a better return for the milk produced on their holdings.

Whilst it is still a fact that the finest quality butter and cheese is produced at the best farms, it is nevertheless true that the bulk compares very unfavourably in quality with that turned out from the factory where skilled labour and scientific methods are in vogue. Much expenditure has been made in teaching butter- and cheese-making for many years past, and doubtless some general improvement in farm-made dairy products has resulted, but on the whole the return has been small in proportion to the expenditure involved. It has indeed become generally recognised that it is better for a group of farmers to start a dairy together, properly equip it and employ the best skilled labour, rather than continue the manufacture of dairy products at home. Better means of marketing are possible, and generally better financial returns are the result.

For the protection of the public, various laws affecting the production and sale of milk have been put into operation recently, and further restrictions on the sale of milk will come into force when what is known as Mr. Burns's Milk Bill, at present before Parliament, becomes law. Parliament, after many years of apathy, has become alive to the need that the nation has of supplies of pure wholesome milk. It doubtless realises that the health of the nation depends greatly upon supplies of pure milk, especially as milk has now become so commonly used in the daily dietary of the great majority, and, moreover, it is the chief food of children, who need most protection.

Following upon the reports of the Royal Commission on Tuberculosis, whose investigations and findings during the last twenty years have shown that tuberculosis or consumption in human

beings is largely caused by tuberculous milk and meat, an order came into force on May 1st by which all tuberculous cattle must be notified. Such cattle are to be examined by veterinary inspectors appointed by the county councils, and on their recommendation all obviously tuberculous animals and cows suffering from tuberculous udders will be slaughtered, compensation to the extent of one quarter of the estimated value of the animal being paid to the farmer where advanced tuberculosis is discovered. Where tuberculosis is manifest but not advanced, three quarters of the value will be paid—in each case half the cost of the valuation and examination to be deducted.

This is an important move in protecting the public, especially children, from tuberculous milk and meat, as unfortunately a fairly large percentage of tuberculous milk is now marketed; indeed, some recent figures of extensive analyses made of London's milk supply showed no less than 10 per cent. of the supply as containing the tubercle bacilli. Municipal authorities can exercise powers to prevent the entrance of milk in towns from any source when it is proven to be tuberculous, but such powers are seldom used. Whilst the Tuberculosis Order will doubtless in a few years result in the killing off of most badly tuberculous cattle, there will still remain the animals that are apparently healthy but are really tuberculous as shown by the tuberculin test. In several instances private enterprise has embarked upon the supply of milk solely from cows which have passed the tuberculin test and are kept periodically tested, which is the only sure way of obtaining a milk supply guaranteed free from tubercle germs.

This alone is not the only part of the scheme, as if milk is obtained pure from healthy cows it must not be allowed to get contaminated from human infection afterwards and before it reaches the consumer, and to prevent this it must be handled and distributed under proper hygienic conditions. There is a minimum Government standard of quality which specifies that if milk contains less than 3 per cent. of fat and 8·5 per cent. of solids not fat it is presumed, until the contrary is proved, that the milk is adulterated.

The law also prohibits the use of any chemical preservative whatever in milk, though harmless colouring matter is not debarred. Recently, too, the use of preservatives in cream has been restricted, and it is now illegal to add any preservative whatever to cream containing less than 40 per cent. of fat. If cream containing over 40 per cent. of fat is preserved, only borax, boric acid, and hydrogen peroxide are permitted to be used, and all receptacles in which such preserved cream is sold must have affixed to them a label printed in letters of a specified size varying with the size of the vessel, stating the preservative used, and if borax or boric acid or both be present, the percentage expressed in terms of boric acid must be stated on the labels. Restaurants and refreshment rooms serving preserved cream are required to display notices to this effect.

THE TURKEY.

The approach of Christmas concentrates public attention on the turkey. The curious identity of the name with the realm of the Ottoman Sovereign, with which, however, the bird has absolutely nothing to do, has rather obscured from public recollection the fact that the bird is distinctively American, and that its first known appearance on any festive board took place in 1519, when Cortez reached the land of the Aztecs and was entertained with royal splendour by Montezuma, and roast turkey figured as one of the most important of the dishes set before the Spanish invader. It was found that the Aztecs had domesticated the turkey to a large extent, and that it was also plentiful as a wild fowl. North of the Rio Grande the bird was equally well known, and Coronado, on his expedition through what is now Texas, Arizona, and New Mexico, found it among the cliff-dwelling Indians and other tribes which he met en route. Among some of the Indians the bird had been known for centuries, the flesh being much appreciated as delicious food, while the feathers served as a favourite adornment for headgear. When the English occupied Massachusetts they found wild turkeys in abundance. In fact, the turkey had its habitat over all that part of the continent where grew its favourite food, Indian corn. From the New World the bird was introduced into Europe by returning Spanish adventurers, and it is possible that more distant States to which it was exported concluded that, like so many other strange things this new fowl came from Turkey and the Golden East. Another explanation volunteered is that the bird may have named itself, as the call of the turkey-hen to her chicks sounds like *tur-r-rk, tur-r-rk.*

The wild turkey of North America, as the Bulletin of the Pan-American Union remarks, is without doubt, the progenitor of all the varieties now spread over other parts of the world. Ornithologists in general hold the aboriginal stock included three varieties, viz., the North American, the Mexican, and the Honduras (*Ocellata*). The bird found in certain forest regions of South America and called curassow, though sometimes designated as the South American turkey, is in reality a member of a different family.

The Mexican turkey, wild throughout the republic (*Meleagris Mexicana*), is short in shank, while the feathers of the body are metallic black shaded slightly with bronze, and all the feathers are tipped with white. The Honduras turkey (*M. ocellata*) is found scattered over most parts of Central America. It is extremely wild, and has a freer flight than those of the north, and is the most beautiful in colouring of all. The ground colour of the plumage is a beautiful bronze green, banded with gold bronze blue, and red with some bands of brilliant black. It can neither be bred successfully nor domesticated. The North American (*M. Americana*) is the original species of the eastern United States. Its colours are black, beautifully shaded with a rich bronze, the broad plumage dark bronze,

brightened with a lustrous finish of copper gold. In the United States six standard varieties of the domesticated variety are recognised and bred. The differences are chiefly in size and colouring.

The turkey, mindful of its former wild state, will not thrive in narrow confines or closed houses, but prefers room and exercise, and a wide range in which to peck about for food. He is not of a bold and adventurous disposition, flies ponderously and with great effort, and only when very much frightened. Nevertheless, as a sprinter he is said to be a great success, and as capable of outstripping a racehorse.

Cortez, so we are told, brought the fowl to Spain in 1520, and as an addition to the feasts of the nobles it was so widely appreciated as to be introduced into all European countries. In France his first appearance seems to have been on the occasion when Charles IX. married Elizabeth of Austria on June 27th, 1570, the *pièce de resistance* having been imported all the way from the then village of Boston in the wilds of America. Time was, they say, when a turkey in America could be bought for 25 cents, or a shilling, whereas nowadays the flesh costs that much per pound. As a favourite dish at Christmastide and on Thanksgiving Day in the United States the turkey is too well known to need comment.

THE "QUARTERLY REVIEW" AND BRITISH CHARITIES.

For the purpose of providing its readers with an earlier review of the various questions concerning the Great War, the usual January number of the *Quarterly* is being published in two parts, of which the first has appeared this month. The second half will be issued as usual in the middle of January.

At the end of the number, and as an introduction to the pages devoted to the advertisements of charities, the *Quarterly* prints the following forcible and eloquent appeal on behalf of a number of benevolent institutions, and of others in like case:—

"The strain is still upon us, is heavier still, is bound to grow. The burden of the greatest war in history already presses, even fiercely, upon all classes and conditions. The heroism of our soldiers and sailors, not to forget the splendid devotion of the men and women who have gone to the fighting places to counteract the cruelties of war, has drawn forth a fine response in service and generosity. Meanwhile, the institutions and charities at home, whose work is more necessary than ever, and whose sources of revenue—at the best not too lavish—have been dangerously re-[illegible]ted through the counter appeals, are endeavouring to continue. They must continue—it is the only word—and the only way to make their position and influence assured is for the stream towards them of donations and subscriptions to keep up."

Then there follow the advertisements of the following well-known hospitals and benevolent institutions: Friends of Armenia, Hospital for Sick Children, London Orphan Asylum, Medland Hall, Royal Alfred Aged Merchant Seamen's Institution, Shipwrecked Fishermen and Mariners' Royal Benevolent Society.

While endorsing this well-timed appeal on behalf of charities who are suffering from the diversion of their usual funds to the urgent needs of the many sufferers from the war, it may be permissible to point out that not charitable institutions alone must lose from the necessary depletion of the sources of supply on which they have to rely. The opportunity may fairly be taken to ask the Fellows of this Society to remember that it also relies wholly for its existence on public support, that it has for years been doing useful national service to education, industry, commerce, and the arts; that its work will be required more than ever when the troubles of war have passed away; and that it has no funds beyond the moderately accumulated surplus of recent prosperous years.

It seems, therefore, not unreasonable to appeal to them and through them to such of their friends as can afford to do so, to help the Society to husband its limited resources, so that its capacity for usefulness may not be crippled by too serious a diminution of its revenues during the short season of adversity which it, in common with the rest of the nation, is fated to endure.

POULTRY AS FARM STOCK.*

The increased production of food supplies is a most important consideration at the present time, and among perishable foods eggs and poultry hold a leading position. Hitherto upwards of 40 per cent. of the annual consumption of these products in the United Kingdom, valued at perhaps £25,000,000 yearly, have been imported. As three-fourths of these supplies are affected by War conditions the need is greater than ever for development of our own resources.

The poultry census of 1908 made it clear that upon the farms and holdings in England and Wales over one acre in extent there were 595 head of adult poultry (inclusive of ducks, geese, and turkeys) per thousand acres of cultivated land. These two countries could maintain three adult fowls per acre without displacement of any other stock or interference with any crop. In addition there are large areas of rough grazings and open lands upon which poultry could profitably be maintained and reared.

Any advance in the cost of foodstuffs is much more than compensated for by the advanced values of eggs. When conditions have returned to the normal, there is no probability that the demand will decline.

* Special leaflet issued by the Board of Agriculture and Fisheries.

Points for the Consideration of Farmers.

Every farmer should increase his stock of poultry as opportunity arises. All healthy, well-grown pullets should be retained as breeding or laying stock, while suitable male birds should be selected for mating later on. In order to economise the food bill, all surplus cockerels or hens should be gradually disposed of except where the hens are likely to be useful as sitters and mothers.

When the stock of poultry on the farm is increased the birds should be distributed over the land and should not be allowed to congregate round the homestead, as that would involve over-crowding and tainting of the soil. Poultry should be moved over the farm in rotation; this would enable full advantage to be taken of the value of the manure distributed by them. (A hundred large fowls will produce four tons of moist manure in a year, worth for many purposes 30s. per ton.)

Apart from the work of hatching and rearing, which should be carried out nearer home, the cost of the management of distributed flocks of poultry is not great. In this direction women and the older girls and boys may be employed. Among farmers' families there are generally some members to whom this work may be committed.

Poultry distributed over the farm would find a large part of their own food, more especially if the position of poultry houses is changed from time to time. Except on poor land or in winter it is only necessary to supply food once a day, preferably in the afternoon when the eggs are gathered. Grain is to be preferred if available. Soft food may, however, be given to effect economy, while household scraps, vegetables, and roots may be used in preparing the mash. Even with an advance in the price of foodstuffs the cost of feeding fowls on farms should not exceed 3s. 6d. to 4s. each per annum.

What Farmers should Produce.

In the majority of cases egg production will be found most profitable, as the imports of eggs are much larger than those of poultry. In 1913 the eggs received from other countries were valued at £9,590,602, and poultry at £992,463.

In one direction farmers can render most important service—namely, by hatching and rearing birds suitable as breeding or laying stock for sale to small holders, allotment holders, and other poultry keepers. In many instances younger members of the family can undertake the work, and build up a connection which should, in the future, be very valuable.

Methods to be Adopted.

Distribution over the land involves the use of portable houses, by which mobility in relation to cultivation can be secured, and the manure produced will thus be utilised to the full. Unless it is desired to retain breeding pens near the farm buildings for special purposes, it is unnecessary to provide runs enclosed by wire netting. In fruit orchards fowls render great service by the destruction of pests which prey upon the fruit trees.

Portable houses can be built or purchased inexpensively. An excellent size is 6 ft. by 8 ft., and 5 ft. high to the eaves. Half of one side should be formed of wire netting, left uncovered all the time, as this ensures light and free circulation of air. To facilitate removal it should be upon wheels and have a wooden floor. Such a house will accommodate twenty-five adult fowls or forty growing chickens.

If eggs are available every hen that becomes broody should be utilised for hatching. In addition one or more incubators should be in use. The following suggestions are important in this branch of the operations:—

(1) As far as possible only selected hens which are over one year old should be used as breeding stock, hardy, active birds being chosen. Those may be mated with a vigorous, early-hatched male bird. Pullets should be kept only as layers until next year.

(2) Eggs to be placed under hens or in the incubator should be carefully selected. Those chosen should be well shaped, with strong shells, and slightly over the average size for the breed.

(3) Where eggs are the chief consideration it is best to mate only hens that have proved to be good layers, or those which as pullets began to lay early in the autumn. The male bird used should also be bred from a hen known to be a good layer. The aim should be to build up a flock with a good laying average.

(4) If table chickens are desired, selection should be from those which develop quickly and which carry an abundance of flesh.

Ducks.

Under normal conditions the raising of ducklings, for early marketing, is very profitable where the work is conducted satisfactorily. Farmers who have running streams or large ponds in which the ducks can find the greater part of their food, may be advised to keep flocks for the sake of the eggs produced, as these can be sold at good prices. Several lots of ducklings should be hatched, otherwise these birds will not prove profitable, as they are expensive to feed. Owing to economic reasons, the demand for ducks will be limited for some time to come.

Turkeys.

With few exceptions the larger farmers have hitherto failed to realise the profitable nature of turkey raising, which is not suited to small holdings as the birds require an abundance of range. It is possible that in spite of reduced imports for the Christmas markets, the demand may be much less than in previous years, and that prices may be comparatively low.

Farmers might take the opportunity of increasing the general stock of turkeys throughout the country. A larger proportion than usual of the young hens should be selected as soon as possible, giving them free range until next spring, and keeping them for breeding or selling them to other farmers for that purpose. As a rule it is

inadvisable to use yearling turkeys for breeding, but the present conditions are exceptional.

On the 14,513 agricultural holdings in England and Wales above 300 acres in extent, comprising 25 per cent. of the total cultivated land, if only one adult turkey were kept for every ten acres, there would be 673,676 birds all told. According to the poultry census of 1908 there were only 172,000 on all holdings above one acre in extent. There is, therefore, very great room for increase.

Geese.

As geese are unprofitable unless they can be fed cheaply, they are not recommended for ordinary farms. Much might be done on common or rough grazing land, where these birds would find their food during the growing stages, and provide a cheap supply for our markets.

Feeding Poultry.

On farms where poultry are at liberty, the birds will find a large part of their food. Much loss arises from supplying food too abundantly. Young birds must be fed until they are able to obtain food for themselves. Older stock should only be supplied with the limited amount of extra food which they may require. Small corn, green foods and roots grown on the place may be given freely. In case of shortage, cut steamed hay (clover hay for preference) is a valuable food; it may be dried off with a little meal. On dairy farms soured skim milk and butter milk are valuable foods for poultry, and may be freely used.

Home production would be greatly increased if agricultural labourers were encouraged to keep a few fowls, and if farmers gave permission for these to run over pastures or arable lands after the crops are harvested. If in this way each agricultural labourer were enabled to keep, say, ten fowls, production would be increased to a very considerable extent.

EMPIRE NOTES.

British Subjects in the United States.—In an article in *United Empire* of this month, on "Who are British Subjects in the United States?" some interesting figures are given, from which it appears that the estimated number of residents in the States who were born in the United Kingdom is 2,573,734, and the number who were born in Canada is 1,204,637, making a total of 3,778,371. Of the males of twenty-one years of age and upwards who have become naturalised, 770,094 from the United Kingdom and 271,762 from Canada have become full citizens, whilst 76,668 and 26,150 respectively have applied for their first papers. This means that about 65 per cent. of male English immigrants of full age and about 54 per cent. of Canadians become naturalised American citizens. This seems to show, and it is natural that it should be so from the closer proximity of their mother country to the States, that Canadians are more tenacious of their nationality than those who come from the British Isles. Applying these percentages to the whole British and Canadian-born population, and making considerable reductions for women who have married, it is found that there are, roughly speaking, about 700,000 persons who were born in the United Kingdom, and about 560,000 who were born in Canada, who are still British subjects, or an estimated total of 1,260,000. The children of these persons, at least of those whose fathers are British subjects, born in the United States, will be subjects of dual nationality. The British-born population is largest in the States of New York and Massachusetts, where 561,000 and 345,000 were born in the United Kingdom, and 120,000 and 297,000 in Canada, respectively. In the other States of the Union there are also large numbers of British-born subjects. In addition to these, there are 2,993,902 persons, born in the States, both of whose parents were born in the United Kingdom and 638,267 whose parents were born in Canada, or a total of 3,289,390, while there are 2,369,112 of whom one parent was born in the United Kingdom and 920,278 of whom one parent was born in Canada. Estimating that only half of these latter parents were males, and therefore capable of transmitting their nationality to their children, it is necessary to halve these figures, which gives a total of 1,644,645. By adding these numbers to the 3,778,371 persons born in the United Kingdom and Canada a grand total of 9,055,785 is reached, from which, however, must be deducted those who have become naturalised, and married women. The net estimated result gives the number of British subjects in the United States (the greater proportion of whom will be of dual nationality) as between seven and eight millions. From these facts the writer infers that the field for the activities of British patriotic societies in the United States is a wide one, and argues the possibility, by attention to this subject and to the opportunities offered at the present time, of drawing still closer the connection between the United States and Great Britain, and of still further promoting the amicable relations between the two countries.

Empire Generosity and Unity. One of the most striking features of Empire generosity and unity in the present crisis is the number and variety of offers and gifts received from some of the smaller colonies and dependencies of the Crown. In a recent number of the *West India Committee's Circular*, under the heading of "Practical Patriotism," reference is made to the offer of £20,000 by the people of Barbados, which, the writer says, "is in accord with the best traditions of that patriotic island, whose proud boast it is that its shores have never been sullied by an invader." In accepting the gift on behalf of the Government, Mr. Harcourt, the Secretary of State for the Colonies, suggested that the most practical form in which it could be sent would be in that of sugar. The Governor of Jamaica appropriately offers, on behalf of the people of that island, a gift

of sugar towards the expenses of the war, which has also been gratefully accepted. British Guiana has started a National Relief Fund, in addition to which the sugar proprietors of that colony, by accepting a price some four or five pounds per ton below the present market price for 60,000 tons of sugar, have made, indirectly, a gift of some £200,000 to the national funds. Trinidad has also opened a fund, and the Bahamas and Bermuda are contributing largely from public and private sources. Other gifts in kind besides sugar are being sent from the West Indies, consisting of oranges, grape-fruit, cocoa, and arrowroot. From Africa, Lewanika, Paramount Chief of the Basutos, sends money to the Prince of Wales's Fund. The Somali chiefs send offers of service, the Emirs of the Northern Provice of Nigeria contribute towards the military expenditure of the Nigerian Government, the Sultan of Sokoto sends a contribution to the Prince of Wales's Fund, as does Sierra Leone. The Falkland Islands and Fiji Islands send money to the Fund, while the latter is also preparing a small expeditionary force. The Maoris of New Zealand are keen to join the expeditionary force of that Dominion, and the Red Indians of Canada are giving money and personal service. Such contributions as these, and many more of a like kind, apart from the great gifts and services of India and of the self-governing Dominions, prove how strongly united the Empire is and how ready to support the Home Government in their great task.

Canada's Trade Outlook and the War.– A well-known American writer, Mr. J. O. Curwood, has been making a study of conditions in the West of Canada in relation to the war. He considers that the war may result in an era of prosperity to that country which it has never known before, not an era of estate boom but of development and growth that will mean practically a new Canada in the West. "For some time," he says, "Canada, if not really sick, has been on the eve of a serious kind of sickness, caused by the fact that her town and city population and values had too greatly outrun her rural population and values"—a statement which may be applied with some, if not equal, force to Australia, where the growth of the city has been far in advance of the rural district, greatly to the disadvantage of the country as a whole. In Mr. Curwood's judgment, the signing of peace will lead to an immigration movement that will amaze the world. After the Franco-German War in 1870, 200,000 Germans settled in three of the greatest American States—Nebraska, Minnesota and Iowa, which are now German-American. He thinks that where one German emigrated then five are likely to do so at the close of this war, but they will not go to the United States, as there are no fit lands open to them there. They, and numbers of emigrants of other European nationalities and of the United Kingdom, will make their way to Canada and South America. We should also say to Australasia as well, as to the Greater Britain of the Southern Seas there is likely to be a considerable movement when peace is concluded. In regard to the prospect of land values in Canada, Mr. Curwood says, "they must increase, and from now on they will increase through steady growth and development." He considers that a great deal of property had been over-sold and that certain places had consequently suffered, but he did not think this over-selling is so serious as some people believe, who forget that "every city that ever became a city had to pass through its period of boom days." This confident and optimistic opinion is largely confirmed by the position and prospects of Canada to-day, notwithstanding the strained monetary conditions from which it has recently suffered and the dislocation of trade, in some departments, occasioned by the war. It has been pointed out, in certain trade journals, that the feeling of pessimism which affected the country on the breaking out of the war has given place to a more assured and optimistic view, arising from the fact that, owing to Canada's inherent strength as a producing country, her inevitable losses in some lines may be more than counterbalanced by her increased profit from others, particularly from produce, which, for the next few years, must command high prices. Strenuous efforts are being made throughout the Dominions to encourage the production of all commodities for which a special demand may be expected. The immediate prospects appear, therefore, to be most favourable. The purchasing power of the farmers is largely increasing, and the appeal of the Dominion and Provincial Governments to put more acreage under cultivation has met with a ready response.

The Transcontinental Railways of Australia.—There are two transcontinental railways in Australia in course of construction—one from Adelaide *viâ* Oodnadatta and Pine Creek to Darwin, south to north, and one from Adelaide *viâ* Port Augusta and Kalgoorlie to Perth, east to west. The main northern line of South Australia terminates at Oodnadatta, and the line for Darwin at Pine Creek. These two termini are to be joined by a railway across the centre of Australia. Good progress, according to recent reports, is being made at the northern end of this projected line, but the line from east to west is being pushed on with much greater rapidity. The rail-head at the Kalgoorlie (Western Australia) end has reached 121 miles. The waterways have been completed to 72½ miles, the concrete work to 80 miles, and the telegraph line for 120 miles. The earthworks had been finished up to 125 miles, the work having been somewhat delayed by heavy cuttings at the 100 miles. On the South Australia side the rail-head is at the 122½ miles, where heavy earthworks have been encountered. A special deviation had therefore to be made, which is about completed. The waterways have been finished to 95½ miles and the telegraph line to 122 miles. The average number of men employed on the south to north extension

is 163, and in the east to west 1,679—1,067 at the eastern and 612 at the west end. The completion of these railways will mark an important advance not only in the railway communication of Australia, but in the development of the areas between the Oodnadatta and Pine Creek, and Port Augusta and Kalgoorlie, and also, in connection with the former, in the opening up of the Northern Territory, which for defence and trade purposes, will be of considerable advantage to the Commonwealth and the Empire.

Bounties to Australian Manufacturers.—According to a return made by the Commonwealth Minister of Customs, published on October 14th, the amount paid by way of bounties to Australian manufacturers during the financial year ending June 30th last, was £51,810 8*s.* These bounties were paid under the Manufacturers' Encouragement Act of 1908. Of this amount, £40,120 18*s.* 7*d.* was paid to G. & C. Hoskin, Ltd., of Lithgow, New South Wales, on pig iron made from Australian ore, and £7,135 13*s.* 2*d.* to the same firm for steel made from Australian pig iron. The remainder of the bounties paid under this Act, £4,553 16*s.* 3*d.*, went to Lysaght Bros. & Co., Ltd., Sydney, for wire netting made from British wire. During the same period a further sum of £13,975 4*s.* 7*d.* was paid under the Bounties Act, but in this there were 88 participants, the largest being F. W. Hughes, Ltd., of Botany, New South Wales, who received £9,083 17*s.* 3*d.* on wool tops, and Whiddon Bros., Ltd.. also of Botany, who received £3,622 4*s.* 11*d.* on wool tops. The sum of £343 17*s.* 3*d.* was paid to sixteen persons on tobacco leaf, for the manufacture of high-grade cigars; £317 17*s.* 8*d.* to forty persons on flax and hemp fibres; and £432 17*s.* 7*d.* to seven persons on dried fruits, except currants and raisins. Under the Shale Oils Bounties Act of 1910, the sum of £328 17*s.* 8*d.* was paid, £278 4*s.* going to the Commonwealth Oil Corporation for kerosene and refined paraffin wax, and £50 13*s.* 8*d.* to the British Australian Oil Co., Ltd., aslo for refined paraffin wax.

GENERAL NOTES.

Memorial Tablets.—The London County Council have issued three more of the pamphlets (Parts XL., XLI., XLII.) recording their work of indicating houses of historical interest in London. The distinguished persons commemorated are Cardinal Manning, Carlisle Place, Westminster; Anthony Trollope, 39, Montagu Square; Lord Tennyson, 225, Hampstead Road; C. H. Spurgeon, 75, Great Dover Street; Robert and James Adam, 4, Adelphi Terrace; and Benjamin Franklin, 36, Craven Street, Strand. Of these the brothers Adam and Franklin are, so far as the Society is concerned, the most interesting, from their association with its history. The account of the Adams contains some new information about their residences, partly supplied from the Society's old records. The note on Franklin records the queer mistake made years ago in the identification of the house, and circumstances which led to the correction of the error. Details of this little backwater of history have already been published in the *Journal* (Vol. LXII. p. 17).

Quantity of Food Required for a Vegetarian Diet.—At a conference recently held at Nice, under the auspices of the Société Végétarienne de France, it was stated that the following menu would afford sufficient nourishment for an adult worker:—

	Quantity.		Price per Kil	Amount
	Grams.	English ozs.	Cents.	Franc.
Cereals or Dried Vegetables . .	150	5¼	60	0·09
Fresh Vegetables	150	5¼	25	0·04
Potatoes . . .	300	10½	15	0·05
Bread	500	17⅝	45	0·225
Olive Oil . . .	60	2⅛	1·35	0·09
			Total . .	0·495
				(or about 5*d.*)

Gold Production in Australia.—The value of the gold produced in the Australian Commonwealth during the period 1851-1911 amounted to £536,196,981, contributed by the various States as follows: New South Wales, £58,760,846; Victoria, £289,663,989; Queensland, £73,739,851; South Australia, £892,810; Western Australia, £103,850,486; Tasmania, £7,245,982: Northern Territory, £2,043,017. The amount of gold produced in the Commonwealth in any one year attained its maximum in 1903, in which year Western Australia also reached its highest point. For the other States in the Commonwealth the years in which the greatest yields were obtained were as follows: New South Wales, 1852; Victoria, 1857; Queensland, 1900; South Australia, 1904. and Tasmania, 1899.

The Popularity of Linoleum in Norway.—The use of and demand for linoleum increases steadily from year to year. No inlaid linoleum is made in Norway. The one factory operating in Norway produces 1,540,000 lbs. (estimated) of printed linoleum annually, valued at £22,000. During 1912 (the latest available statistics) there were imported from the United Kingdom and Germany 2,554,454 lbs. of inlaid linoleum, valued at £50,000, none coming from other countries. The increasing demand for linoleum seems to be

the result of a spreading sentiment in favour of sanitary precautions. In the case of Christiania it is estimated that 80 per cent. of the population live in rented homes. Where there are hardwood floors linoleum is not used, but in much the greater part of rented buildings or apartments the tenants insist on either hardwood floors or floors covered with linoleum. As a result, the floors of the greater part of rented apartments are covered with linoleum by the landlords. Sometimes rugs are laid on the linoleum; in many and an increasing number of cases neither rugs nor carpets are used. The linoleum or hardwood floors are cleaned and waxed daily, Norwegian homes being proverbially neat and clean. The tendency is towards single colours without figures of any kind, or at least not very pronounced figures. Tints now preferred are neutral green, red, and brown.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 20.—J. A. Hunter, "The Textile Industries of Great Britain and of Germany." Lord Rotherham, President of the Textile Institute, will preside.

January 27.—Hon. John Collier, R.O.I., "Portrait Painting." Lord Sanderson, G.C.B., K.C.M.G., will preside.

February 3.—Octavius Charles Beale, Chairman of the Australian Manufacturers' Association, "Imperial Industrial Development after the War."

February 10.—F. Vincent Brooks, "British Lithography in 1915."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 21.—Henry John Elwes, F.R.S., "Nepal." The Right Hon. Sir Herbert Maxwell, Bt., F.R.S., will preside.

February 11.—Captain Sir George Duff Dunbar, Bt., I.A., "Tribes of the Brahmaputra Valley."

March 18.—Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army."

April 15.—M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 26.—Major E. H. M. Leggett, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda."

February 2.—Edward R. Davson, "Sugar and the War."

Dates to be hereafter announced:—

Thomas Worthington, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. Thorne Baker, "The Industrial Uses of Radium."

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. Hulme, "Patent Law."

H. M. Thornton, "The Industrial Uses of Coal Gas."

D. Y. Cameron, A.R.A., R.E., "Etching."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

William Poel, "Shakespeare's Profession."

Arthur Wilcock, "Designing for Textiles."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

April 15, May 13.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March, 2, 30, May 4.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Dr. F. Mollwo Perkin, F.I.C., F.C.S., "Oils, their Production and Manufacture." Three Lectures.

January 18, 25, February 1.

M. H. Baillie Scott, "House Building-Past and Present." Three Lectures.

March 15, 22, 29.

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Fothergill Lectures.

Monday evenings, at 8 o'clock:—

Professor Vivian B. Lewes, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

February 15, 22, March 1.

Juvenile Lectures.

Wednesday afternoons, at 5 o'clock:—

H. Plunket Greene, "How to Sing a Song." Two lectures, with vocal illustrations.

January 6, 13.

Journal of the Royal Society of Arts.

No. 3,241. VOL. LXIII.

FRIDAY, JANUARY 1, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 6th, 5 p.m. (Juvenile Lecture.) H. PLUNKET GREENE, "How to Sing a Song."

The lectures will be accompanied with numerous vocal illustrations.

Special tickets are required for these lectures, and no person can be admitted without a ticket. A few tickets are still left, and these will be issued to Fellows who apply for them at once.

Further particulars of the Society's meetings will be found at the end of this number.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, December 17th, 1914; SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., in the chair.

The paper read was—

THE INDIAN INDIGO INDUSTRY.

By F. MOLLWO PERKIN, Ph.D., F.I.C., F.C.S.

About this time last year the late Mr. Popplewell Bloxam was to have read a paper on "Natural or Plant Indigo," and had already practically finished writing the paper when his untimely death occurred. From the slides which Mr. Bloxam had had prepared, it is evident that he had intended in the first place to describe the method of production of indigo, and I have also decided to give a brief description of the manufacture of the dye from the indigo plant, because, although some present will be familiar with the process, there are others who may not be. By the kind assistance of the Secretary of the Indian Section I have been permitted to make use of the slides prepared for Mr. Bloxam from photographs taken by Mr. H. Martin Leake.

Mr. Bloxam was a believer in the possible resuscitation of the Indian indigo industry, and he intended to urge on the planters more vigorous efforts in research, both chemical and agricultural. Since last December great changes have taken place owing to the terrible war into which the world has been plunged. In consequence of the cessation of the supplies of synthetic indigo, which is a German product obtained entirely from Germany, Indian indigo is at a premium, but unfortunately it is only possible to obtain it in comparatively small quantities, and this is causing great inconvenience to the dyers.

Indigo, being one of the fastest of blue dyes, and having peculiar properties of resistance to light and weather conditions, is used in very large quantities for dyeing the cloth used in making the clothing of our sailors and also for dyeing serges in general.

In 1895-96 the total value of plant indigo produced was £3,566,700, and the acreage under cultivation 1,339,099 acres. Last year, owing to the competition of synthetic indigo, the value had fallen to £60,000- £70,000, and the total acreage under cultivation had been reduced accordingly.

The cultivation of the indigo plant and the production of the blue indigo dye is one of the oldest industries. Certain blue cloths obtained from Egyptian mummies more than 5,000 years old were found to be dyed with indigo.

Pliny described it under the name of *Indicum*, and said that it was used as a paint and came from India. It was not, however, until the sixteenth century that indigo was introduced into Europe, and then its introduction was very slow owing to the opposition of the woad cultivators. As a matter of fact, the blue colouring matter obtained from woad is indigo. The opposition of the woad cultivators was purely due to their desire for self-preservation. They contended that the dye from Indian indigo was fugitive and was a dangerous and pernicious drug, and in fact were successful in obtaining legislation making its use punishable by heavy fines.

The plant from which indigo is obtained only flourishes in hot climates. Consequently it can only be cultivated in tropical countries. The largest quantity of indigo has always come from India, particularly from the Provinces of Bengal, Madras and Oudh. The plant is also grown in Java, and the indigo manufactured there has a very much higher percentage of the blue colouring matter, indigotin, than that produced in India. Small quantities are also cultivated in Central America, Japan, China, Brazil, and in some parts of Africa.

The indigo plant, in order to flourish satisfactorily, requires certain conditions. The season must not be too wet or too dry. If the season is wet immediately after the seed has been sown it mildews and is spoilt and re-sowing is necessary. In bad seasons the crop may require to be so re-sown several times. The seed is usually sown in February or March, but much rain during these months will necessitate postponing the sowing, and thus a late crop will be obtained. The ground upon which the indigo is to be cultivated is prepared at the end of the "mahai," or manufacturing season, which is towards the end of October and during November. Great care is taken to prepare the surface of the ground suitably. The weeds, etc., are first removed by means of hoeing, after which the land is ploughed by means of bullock-drawn ploughs, which first furrow lengthways and then across at right angles. A "hanga," that is, a heavy wooden pole, is then drawn across the broken-up ground. This serves the double effect of breaking the clods and of smoothing down the soil. The land may then be ploughed over again several times, each time being run over by the "hanga." By this means it is broken down to a very fine state and is then very often rolled over so that a good top surface is formed which prevents the rapid evaporation of the moisture. In February or March the seed is sown by means of drills.

There are several varieties of the indigo plant, the most important being *Indigofera tinctoria*, and *Indigofera anil*. These were until lately the chief varieties cultivated in India. *Indigofera arrecta*, which is the variety used in Java, has in recent years been satisfactorily introduced into India with improved yields of the dye. *Isatis tinctoria*, or woad plant, is the variety grown on the West Coast of Africa. It is also to a small extent grown in Lincolnshire and on the Continent. It is not, however, cultivated for the extraction of the dye, but is used in fermentation vats in dyeing woollen goods.

The indigo plant is herbaceous, and grows to a height of from three to four feet, having a single stem about half an inch in diameter. The plant belongs to the natural order Leguminosæ. Consequently it is able to obtain a portion of the nitrogen required for its nourishment from the air. This is a very important fact, because as a rule the soils in which indigo is cultivated contain only small quantities of nitrogen. It might, of course, be increased by manuring, but this has never been done to any great extent. The manure chiefly used is the air-dried refuse of the indigo plant which is left behind after the indigo has been extracted, and is called "seet."

Generally speaking, the indigo plant is ready for harvesting about the middle of June, but if the sowing has been early and the weather conditions have been satisfactory, it may be ready at the commencement of the month. On the other hand, bad weather conditions may have a retarding influence on the growth, when it will not be ready for cutting before the end of June. The process of cutting and manufacturing is, in the main, carried out under European directions, but native labour is employed, and the falling off in the production of indigo has caused considerable unemployment. The plant as it is cut is tied into bundles, placed on bullock-waggons, and immediately taken to the steeping vats. These vats are built of brickwork lined with concrete or cement. The bundles of plants are packed into vats in a more or less upright position to allow the air and gas bubbles produced by the subsequent fermentation to be readily liberated. When the vat has been packed bamboo canes are placed across the top of the green plant and held in position by stout balks of timber which are fixed to the sides by means of iron pins. Water is then run in to within five or six inches of the top of the bundles. As the steeping proceeds great expansion of the

plant takes place, and an immense pressure is exerted on the beams, which occasionally are fractured, or the sides of the vat sometimes give way under the pressure. After steeping for a few hours fermentation sets in. The fermentation is induced by an enzyme contained on the leaf of the plant, which is known by the name of "imdimulsin"—just as the grape skin contains the enzyme or ferment necessary to cause the fermentation of the sugar contained in it to alcohol. The rate of fermentation varies with the temperature of the water. Usually the temperature of the water in June and July is from 88° to 94° F. If the temperature is lower—as, for example, in September when the second crop is treated—a longer steeping is necessary. As the fermentation proceeds bubbles of gas—mostly carbon dioxide—are given off and the surface of the liquid presents a foamy appearance. Towards the end of the operation inflammable gases—hydrogen and marsh gas—are given off. At the end of ten to fifteen hours the vigour of the fermentation subsides, and this indicates to the practised overseer that the steeping should be stopped. The tap or valve into the beating vat is now opened, and the liquid run out as rapidly as possible. At this stage the liquor has a colour varying from a pale to a golden sherry yellow. The more golden the colour the greater the yield of indigo. It often happens, however, that the lighter coloured liquor, although giving a smaller yield of indigo, gives a purer product.

In the beating vat the liquor is agitated and splashed, so that it becomes mingled with the air. The beating is often done by natives, who stand in the vat armed with wooden paddles. It is now, however, more frequently carried out with paddle-wheels actuated by steam power. Soon after the beating has commenced the colour of the liquid becomes greenish, and finally deep blue, owing to a fine precipitate of indigo blue being formed. To ascertain when the beating has been carried out sufficiently a small portion of the liquid is poured on to a white plate. If the indigo sinks to the bottom rapidly leaving a clear supernatant fluid the operation is finished. If a strong current of air is forced through the liquid in the vat better results are obtained than by beating, and in some cases this is done.

After the beating is completed the indigo is allowed to settle, which generally requires from two to four hours. The bottom of the vat is inclined towards one end, so that the indigo as it is precipitated collects at this end. As soon as the separation is complete the water is run off from above the precipitated indigo. This water is called "seet water." The indigo precipitate, or "mal," as it is termed, is passed through strainers in order to hold back any twigs or leaves which may have found their way into the beater. It is then run into a well, and from there raised by pumps or steam-injectors through strainers into the boiling tank. The temperature here is raised to nearly boiling point, or sometimes the mixture is actually boiled, generally by means of steam. The boiling kills putrefying ferments, dissolves out some of the foreign matters, and causes the solid indigo particles to separate out more rapidly. Sometimes the supernatant liquid is drawn off, clean water added, and the temperature again raised. It would probably be a good thing if the second washing and boiling were always carried out. After the indigo has settled, the bulk of the water is run off and the indigo sludge is run on to the dripping vat. This consists of stout cloth fixed on a wooden frame with sides about one and a half feet high. The excess of water drains off here and a pasty mass is obtained, which contains from 9 to 11 per cent. of indigo blue.

From the filters the indigo pulp is run into the presses, which consist of rectangular boxes with perforated framework. The box is lined with closely-woven cloth made specially strong to withstand pressure. The paste is run in to a sufficient depth to produce—after the water has been pressed out—a cake about three inches thick. The cloth is then folded over and the top of the press very slowly moved down by means of a screw worked by strong levers. The pressure must be very carefully exerted, otherwise the cloths will break and the indigo pulp will be squirted out and wasted. When water ceases to flow out the pressure is slowly removed, and the pressed slab placed on a frame and cut in cubes with brass wire in a similar manner to that employed for cutting cheese. Each cube is roughly three inches square, and is stamped with the mark of the firm. The cubes still contain a considerable quantity of moisture, 68 to 70 per cent., and before being placed on the market they must be dried; indigo as received in Europe usually contains from 4 to 6 per cent. of moisture. In order to dry the cubes they are placed on shelves about half an inch apart, and left to dry for a period of two or three months. The sheds in which the cubes are placed allow of free access of air, but it does not do to have too free a circulation,

otherwise the outside portions dry too rapidly and the cakes fissure and break, and lose in market value. As the drying takes place the indigo becomes coated with a mouldy fungus, and at the same time ammonia is evolved. When thoroughly dry the cakes are brushed and then packed into strong cases and sent to the market.

After the indigo plant has been cut, fresh leaves sprout out, and at the end of two or three months a second crop of the plant is cut. The first crop, which is the principal one, is called the "Mohan," and the second crop the "Khoonties." It sometimes happens, if there has been much drought when the first crop was maturing, that the second crop gives a better yield of indigo than the first crop.

Indigo blue does not exist as such in the plant, but is there combined with a sugar—dextrose—in the form of a substance called a glucoside, the name of this sugar-bearing substance being "indican." This glucoside is, however, very unstable, and is readily split up into its compounds—sugar and indoxyl, which latter, on oxidation, yields indigo.

1. $C_{14}H_{17}NO_6 + H_2O = C_6H_{12}O_6 + C_8H_7NO$
Indican Water Glucose Indoxyl

2. $2C_8H_7NO + O_2 = C_{16}H_{10}N_2O_2 + H_2O$
Indoxyl Oxygen Indigotin Water

In the processes just described the breaking-down of the indican into indoxyl was produced by fermentation induced by the enzyme indimulsin. The oxidation of the indoxyl to indigo blue or indigotin is brought about by the beating process. Acids or alkalies also have the power of breaking up the indican and resolving it into glucose and indoxyl. As a matter of fact, the process does not work quite so smoothly as shown above. The indigo blue is never obtained pure, but is contaminated with greater or less quantities of brown and generally red-coloured substance, also with a gummy substance called indigo glutin.

From the foregoing description of plant indigo, it will be gathered that the method of manufacture of natural indigo is rather crude, one might safely say very crude. It is doubtful whether, even now, after the disastrous competition of the synthetic product, the methods employed are very much superior to those in use when the winding-sheets of the Egyptian mummies were dyed. One of the difficulties the planters have had to deal with has been the large number of cranks and charlatans who have come to them with schemes which only required to be tried or to be looked at by a capable chemist to show their worthlessness. The planters once bit were many times shy of displacing a method which they understood by one which might mean great financial loss However much we might realise their difficulties when the production and introduction of synthetic indigo on the market was *un fait accompli*, they knew as far back as 1880 that indigo had been synthesised, and they ought to have known how artificial alizarin, introduced in 1869, killed the madder industry in a few years. I say "ought to have known," because I very much doubt whether, outside indigo, they knew or cared about any other dye. As far as indigo was concerned they probably argued "the ancient mummies were dyed with indigo, and that was 5,000 years ago; we are to-day making great profits out of the same indigo. Is it likely that this product just invented can ever drive our indigo out of the market in our time?"

Now the question arises, Is it possible to save the Indian indigo industry? Probably a thousand years hence indigo blue will still be used, as we have discovered no other dye with similar properties; but will it be made synthetically or will plant indigo be used? I should like to think it will be the natural product; but look at the difficulties.

The amount of the blue colouring matter obtainable from the indigo leaves probably does not, as a rule, exceed 1 per cent. In the process of manufacture it is doubtful if more than 50 per cent. of the colouring matter is obtained—the rest is lost. The cake indigo, when placed on the market, varies enormously in purity. Good samples of Bengal indigo may analyse 62 to 66 per cent. of indigotin, whereas some indigos are as low as 30 per cent. Java indigo is often 70 per cent. and sometimes as high as 76. It is claimed that it is sometimes as high as 90 per cent., but I never yet came across a sample of such high purity. As a matter of fact, in spite of the much higher purity of Java indigo, the dyers, as a rule, prefer Bengal indigo. This is probably due to the much higher percentage of red indigo which is usually present in Java indigo. Contrast this with synthetic indigo, which can always be placed on the market with a guaranteed indigotin content. It can either be bought as a powder or in the form of a paste. Another great difficulty which the indigo planter has to deal with is due to meteorological conditions. Thousands and thousands of acres of land may have been planted with indigo seed, but

who will guarantee a good crop? There may be no rain, there may be too little sun, or there may be too much sun. If there were no synthetic indigo, probably the planter would not mind much—he would get a higher price for his product. But when he is confronted with a product which is manufactured from start to finish in a factory and which is absolutely unaffected by climatic conditions, he is in a similar position to a battleship outranged by the enemy's guns. One bad season which prevents him being able to supply the demand may be sufficient to lose him the bulk of his markets. The dyer may say—"I prefer the natural indigo; it dyes a deeper shade, or it penetrates the fibre better; but when I most want the dye I cannot be sure of obtaining it." With synthetic indigo it is not so. The factories are always able to increase their supplies to meet the demand.

The subject of my paper is natural and not synthetic indigo, and it is not my intention to describe the various methods of manufacturing the synthetic product. In any case I could not improve on the splendid paper read before the Royal Society of Arts in 1901 by Professor Meldola. At the same time, to ignore this magnificent chapter of research and chemical industry would be out of place, particularly as it is a factor the planter cannot ignore. While the indigo planter and indigo merchant slumbered, the busy brains of highly-trained chemists and engineers were following up first one path and then another in order to solve the problem of the manufacture of synthetic indigo on a commercial scale. It has often been stated that the object of the research chemist is to multiply new products, and that so long as a new substance is obtained he is satisfied. That attitude most certainly was at one time taken to a considerable extent by those who worked in university laboratories, particularly in this country. I doubt if it was ever the feeling of the chemist working on the Continent. At one time there was a tendency for the scientific worker in Great Britain to look down upon those who he said were simply doing research work with the object of making money. "Fancy," they said, "carrying out research work because its ultimate end may mean the amassing of wealth! We do our work for the love of science and for the advancement of science." This attitude had at one time a great deal to do with the position taken up by the manufacturer. He naturally considered that men who thought in this way would not be of any value in a factory, and would simply spend their time in the laboratory and not attend to the details of putting a process on a commercial basis. The British manufacturer is always blamed, and there are very few who will take up the cudgels on his behalf. In the chemical industry his sins are very great, but I maintain that the men of science in this country must also share in the blame. I suppose this is rank heresy, but as I believe that both the manufacturer and man of science have to turn over a new leaf and collaborate whole-heartedly and without jealousy, I think it only fair to state my belief.

There is nothing more exhilarating than gradually to develop a process. To commence with a few grains in a test-tube; to prepare a few ounces, then a few pounds, and from pounds to hundredweights and tons, so that finally a commercial process results—that is research in its highest form. Look how it benefits the community. It is said that he who can cause two blades of corn to grow where before there was only one is a benefactor to mankind; and in a similar manner he who, by laborious research work, is able to enrich his country by a new discovery and by a new manufacturing process, deserves well of that country. What was the attitude of the Indian indigo planters when indigo was first synthetised in the laboratory? They adopted a sceptical attitude; they knew how to manufacture indigo from the plant. It was not possible that a product produced in the leaves of a plant, fertilised by the rains from heaven and by the light of the sun, could be produced from tar distilled from the coal. They sat still. Their money came in regularly until in 1898, as one planter stated, they were startled by a bolt from the blue.

It was in 1880 that Baeyer first completely synthetised indigo, employing toluene as the starting product from which, by a series of steps, phenylacetic acid was prepared, and by another series of reactions ultimately isatin and then indigo were obtained. In the same year he discovered the cinnamic acid method, the starting point for which was again toluene. Before 1875 cinnamic acid was obtainable only in small quantities from natural products such as balsam of tolu, and was a rare product. In that year, however, a process was discovered in this country whereby it could be produced by heating benzaldehyde with acetic acid and sodium acetate. The starting product for benzaldehyde is toluene. The first patent for indigo was taken out in March, 1880. This fact seems to have caused considerable uneasiness amongst the Indian planters. This process and

many succeeding processes were, however, too expensive for the synthetic indigo produced to compete with the natural product. Consequently the planters, with crass ignorance of the previous feats of chemical research, took no further heed, went on as before, and made no efforts to improve the antiquated process for producing plant indigo.

In 1879 my father gave a series of lectures on the history of alizarin, and said, in his concluding remarks: "One very important colouring matter related to coal-tar, and one of the original sources of aniline—a product of as great importance as alizarin—has yet to be produced on a large scale. I refer to indigo. Baeyer has shown that it can be produced artificially, but at present no practical means of accomplishing it have been discovered. No doubt, however, it will not be many years before this is achieved, and the cultivation of the indigo plant share the fate of madder."

That was probably the first of the warnings, but many other warnings were sounded in subsequent years as process after process was developed and patent after patent taken out.

In 1898 synthetic indigo was placed on the market at a price which enabled it to compete with the natural product. Then, indeed, the planters did waken up. There were cries for help, and fevered efforts were made to improve the methods of manufacture. Like most fevered efforts, they were unfortunately spasmodic. Nearly twenty years had been employed in developing the synthetic process, and nearly £1,000,000 sterling had been spent before a pound was placed on the market. If, during that time, patient research had been carried out in India there is very little doubt that the process would have been improved and larger yields of indigo obtained per acre of land cultivated. The Dutch have had greater foresight than the Indian planters. Indigo from Java has a much higher indigotin content than Bengal indigo, and is more uniform in quality. The reasons are that:—

(*a*) The land is better irrigated.

(*b*) Different method of planting. The seed is sown in protected areas, and when the plant is about six weeks old, and able to stand changeable weather conditions, it is planted out. It has already been mentioned that much rain or much drought directly after sowing in India necessitates re-sowing.

(*c*) Soft water is used in fermentation.

(*d*) The areas planted are smaller than those in India, and are consequently more easy of control.

Although Java indigo contains a higher percentage of the blue colouring matter indigotin than Indian indigo, it is not generally liked so much by the dyers as a good Bengal indigo.

It is often stated that synthetic indigo is not the same body as natural indigo. So far as the blue *indigotin* is concerned there is absolutely no difference. Indigotin, whether obtained synthetically or by extraction from natural indigo, is identically the same body. Synthetic indigo is practically pure indigotin. Natural indigo is a mixture of indigotin, indigo red, indigo brown, and a glutinous substance. Sometimes there are small quantities of indigo yellow. Besides these organic substances there is also mineral matter, sometimes in very considerable quantities. It is claimed that the presence of the other organic substances mixed with the indigotin is an advantage, and that not only does the indigo penetrate the goods better, but that the vat will go a longer way than when a synthetic indigo is employed. It is also claimed to be faster to light. It is certain that many dyers prefer it, but I have not, as a rule, found any tendency for them to agree to take only natural indigo when they can obtain the synthetic product equally well. The synthetic indigo is easy to manipulate. It comes on the market in the form of a fine powder or in a paste of guaranteed percentage of indigotin. Personally, I have not always found it come up to the guarantee.

The Germans were not content with manufacturing synthetic indigo. They also experimented with the best means of reducing it and preparing a good working vat. Indigo itself does not dye, because it is insoluble in water. If, however, it is reduced, the blue colour vanishes and a pale yellow solution containing indigo white is obtained. On exposure to air, oxygen is absorbed and indigo blue again obtained. If wool is steeped or passed through this vat and exposed to the air, the indigo white is oxidised *in situ* and the wool becomes dyed blue. The Germans, therefore, carried out research in order to find the best vats which could be used with synthetic indigo. Having found them they not only supplied the indigo, but also sent their chemists round to the dyers to show them how to make and use these vats. Could anyone imagine a planter devising a vat, or sending round to show how the vat should be used? I have not come here to anathematise the planters or anyone connected with the manufacture and use of natural indigo; but it is necessary to point out why the Germans have obtained their ascendancy.

To my mind it is a very sorrowful fact that no British chemists have had anything to do with the elucidation of the synthetic indigo problem.

Now the question arises—and it is one of the greatest interest to those who are present—Is it possible to save the Indian indigo industry? At present we are at war with Germany, the producer of synthetic indigo. How long that war will last it is impossible to say, but, in the meantime, dyers are crying out for indigo. The present quantities of natural indigo are wholly inadequate to satisfy the demand. Are the planters prepared largely to increase the acreage under cultivation? If one goes to the capitalist in this country and says: "We require aniline dyes and, if we had the money, could manufacture them," the reply is that Germany has for years held the monopoly. If we start manufacturing now during the war there will be no difficulty in selling the dyes; but what about after the war? I understand that is also the attitude of the Indian planter. "If I cultivate more land for indigo, increase the size of my factory, and sell at good prices during the war, what about after the war? Will the Government and will British dyers guarantee to take the natural product when they are offered the synthetic?"

An appeal has been made to the Government to use only Indian indigo for the dyeing of all Government contracts. In this appeal it is stated that fifteen years ago the value of Indian indigo was between £3,000,000 and £4,000,000; and in 1914 the value was between £60,000 and £70,000. Although I am in complete accord with the objects of this petition, and hope most sincerely that the Government will see their way to employ the natural product for dyeing the uniforms of Government servants in the Army, Navy, Post Office, the Police, etc., I must, as a chemist, take exception to the expression "German chemical substitute." Synthetic indigo is not a substitute; it is precisely the same indigotin as that obtained in natural indigo. Nor am I prepared to agree that synthetic indigo is poisonous. I think it is a great pity that these two irrelevant statements have been made. They weaken and do not strengthen the case.

Personally, I believe that for many classes of material better results are obtained with natural indigo than with synthetic indigo.

One very important consideration in reference to the production of natural indigo is an economic one. In many cases the land which was previously cultivated for indigo has been planted with the sugar-cane or with oil-seed plants. Now which pays the planter the better—to cultivate sugar and oil-seed plants or to cultivate indigo? If the indigo gives the smaller return on his capital, he certainly will not go back to cultivating it simply from patriotic reasons. I am also afraid that the dyer will not go back to using it in place of the synthetic product if the latter is easier of manipulation and the supply more certain.

Undoubtedly it will pay the planter for the next two years to increase the output. There cannot, however, be any increased quantity on the market before this time next year. The ground has to be prepared; in fact, should have been prepared now. Has a larger acreage been prepared, so that the seed can be sown in February or March? I am told that the weather, before the tilling of the soil took place this year, had been too dry. That will militate against a good crop.

Owing to the recent curtailment in the area of ground cultivated, it is doubtful whether there is sufficient seed obtainable to raise a very much larger crop for next year's manufacture. What, then, is to be done? Indigo is wanted and wanted in large quantities, and at once. As just mentioned, no fresh supplies other than those just coming on to the market can be obtained until this time next year, and it does not appear that next year's supplies will be sufficient to meet the demand. The work of Bloxam and his colleagues points to the possibility that better yields of indigo could be obtained by improving the methods of fermentation. When the indigo plant is steeped, fermentation takes place and the glucoside is split up into glucose and indoxyl, which the subsequent beating converts into *indigotin*. Unfortunately, however, degradation products of indigotin, such as indigo-brown, are produced at the same time, thus reducing the yield of the blue colouring matter. Whether they are produced by the further action of the enzyme indimulsin or by other ferments, which is very probable, is not yet known. A more thorough study of the fermentation process on the spot might, however, elucidate this. If the indigo planter is to put the production of natural indigo on a firm foundation, it will not be merely a question of making money while the war is on and prices are high; it will be a question of improving the methods so as to get higher yields of indigo and thus reducing the price. It is also important that the improved conditions should, as far as

possible, give an indigo of standard quality. To fix a standard is admittedly difficult. It does not follow that an indigo of high indigotin content necessarily gives the best results when used by the dyer. An indigo analysing, for example, 62 per cent. indigotin, may give equally good results in the vat as one analysing 67 per cent. This may be due to some particular impurity in the indigo of higher indigotin content, or to the presence of some material in the one of lower analysis which aids its penetrative action into the fibre. These, of course, are matters for research. They certainly do seem to point to some differences in the vats made from natural and synthetic indigo.

The method of analysis at present used is a modification of Rawson's process. It requires great care and considerable practice to obtain concordant results. There is also the tetra-sulphonate method of Bloxam which, when properly carried out, gives the absolute indigotin (that is, the indigo blue) content. The Rawson method always gives higher results than those which are obtained from that of Bloxam. The reason is that not only indigotin is oxidised by the permanganate, but also small quantities of other organic bodies such as indigo glutin. Indigo is, however, analysed by the Rawson method in India and the analysis sent forward with the overland samples. The indigo is sold on the analysis, and should any great discrepancy be found between the analysis in India and that here it is awkward for the broker. Another point, of course, is that natural indigo is not pure indigotin but a mixture of indigotin, indigorubin, indigo brown and indigo glutin. The Bloxam method has also shown that synthetic indigos are very frequently below standard in their indigotin content. Generally speaking, I employ the modified Rawson method, but as a check between two indigos for actual indigotin content I employ the Bloxam tetra-sulphonate method.

Other important points which may even at this late hour help to prolong the life of the industry may be summarised as follows :—

(*a*) Selection of seed and the propagation of the qualities which yield the highest percentage of indigotin. In this connection it must be remembered that one seed is best suited to one district and another to another district, owing to differences in the soil and climatic conditions.

(*b*) Chemical improvements in the manufacture. These must not be carried out haphazard, and if results are not immediately shown the planters must not get impatient, and after a short trial say, "What good are you doing?" and get rid of their chemist. Remember the eighteen years and the huge sums of money spent, and the patient work of the German chemists, before they were able to produce synthetic indigo.

(*c*) Economy in management.

(*d*) Agricultural experiments with different fertilisers and the rotation of crops.

The wonderful development of the beet-sugar industry was very largely due to improvements in agricultural methods. When the industry was first started the amount of sugar in the root was not more than 6 or 7 per cent. By improvements in fertilisation and selection of the best plants the yield is now more than 14 per cent.

A large amount of most valuable research work on indigo has been carried out at the University of Leeds by the late Mr. Bloxam and his colleagues, and if some of the most important conclusions arrived at are tested in India on a commercial scale good results should accrue.

In conclusion, I feel constrained to say that in my opinion the Government should insert a clause in all their contracts where indigo blue is to be employed for dyeing that only natural indigo should be employed. If after a few years' trial it is found that the indigo planter is unable to meet the demand, and if it can be proved that better results can be obtained with synthetic indigo, then the natural indigo industry —like the natural alizarin obtained from the madder plant—must cease to exist.

My advice now is—let the indigo planter take his courage in both hands and prepare and sow largely increased tracts of land. This, at any rate, will relieve the shortage; it will also show the Government that Indian indigo is obtainable in sufficient quantities to meet the demand. Concurrently with the production of larger quantities of indigo let him put part of the profits to a research reserve. Then perhaps the Indian or Home Government will also aid with pecuniary help. Unless the manufacturers of natural indigo are prepared to work on scientific lines in all round improvements of the methods —agricultural and chemical—I see no possibility of increasing or even retaining the industry.

DISCUSSION.

THE CHAIRMAN (Sir Steuart Colvin Bayley), in opening the discussion, said it was nearly fifteen years ago since he was present in the room when a paper on the subject of indigo was given by Mr. Rawson. The chair was occupied on that occasion by one who had recently passed

away, and who had been an intimate friend of his own. That gentleman had been the best leader the planters had ever had, whether in the field or in the council room, whether as presiding over the Planters' Association or as colonel of the Bihar Light Horse. In his own district he had been a man of extraordinary influence, which he always exercised wisely and well. He referred to Sir William Hudson. At that time—some fifteen years ago—the situation was in some respects similar to what it was at present, and in other respects very dissimilar. The planters suddenly began to realise what the production of synthetic indigo and its being brought on the market meant to them. The battle between the chemistry of Nature, backed by rule of thumb, and the chemistry of science, backed by scientific methods of manufacture, had commenced; and already it was very obvious to which side the victory would incline. The planters called for help. The Government gave them what little help they thought proper and expedient. The planters called for help from chemists, and they got good chemical advice. But with what result? Of the measures taken, some were insufficient and the others were too late. That was all that was to be said then. The following year there was a paper given, not specifically upon indigo, but upon the chemistry of aniline dyes generally by Professor Meldola. In that paper, although it was almost entirely technical, Professor Meldola went at some length into the methods by which synthetic indigo had been arrived at, and he showed not only the extraordinary ability but the marvellous patience, tenacity, co-ordination, and co-operation between capital and science which, after eighteen years' work without any financial result, and after the expenditure of nearly a million pounds, succeeded in bringing synthetic indigo on the market, and Professor Meldola asked very naturally how a thing of that kind could be worked in England. Again, only a fortnight ago a paper had been given before the Society by Dr. Ormandy upon the same subject — the question of the possibility of capturing the trade in aniline dyes, now that the German factories were practically closed. That paper was really intended to mean, no doubt, "Wake up, England!" But it was a real denunciation in no mild terms of everybody: a denunciation of the Government, a denunciation of Government officials, a vigorous denunciation of capitalists and of their outlook upon science, a denunciation of merchants and of banks; and the general result to his (the Chairman's) mind was one of extreme depression. The result would be not "Wake up, England!" but "Haul down your flag; it's no use." He referred to those papers to show that in all three cases the fault pointed out was the want of co-operation between science and capital. He was very glad to hear Dr. Perkin say a few words in justification of the merchants and manufacturers. He also thought a few words should be said on behalf of the poor planter. He recollected discussing with Sir William Hudson that very question forty years ago. At that time there was no danger, as far as was known, from synthetic indigo; but there was a danger of aniline substitutes bringing down the price of indigo, and he asked Sir William whether it was not possible for the planters, as a body, to employ a staff of agricultural chemists. Sir William consulted two or three planters, and the result was that the idea was negatived, not merely from apathy, but from real reasons. One was that the whole industry of indigo planting was not a co-operative industry, but strictly individual, and each man worked for himself on his own lines. Another point was that the planters were not always owners of the factories, and it was not always possible for them to combine in any matter in the absence of the real owner. As he had said, there was a certain similarity in the situation then as there was now. Planters were again asking for Government help and for the advice of sound agricultural chemists, but there was this difference. At that time the export of indigo was between £3,000,000 and £4,000,000, and at present it was between £60,000 and £70,000. Again, formerly there were 700 Europeans employed in the industry. Altogether the circumstances had changed. The question now arose, Was it worth while to try to recapture the trade? Dr. Perkin had given very sound advice on that point, but the first point to consider was how the planter could afford to set about it? To begin with, what were the present conditions of the structures—of the steeping vats, and the beating vats, and the drying houses? How much would it cost to put them into proper order? What had become of the planters' main stand-by, the Zeraats—the home-farms, as it were—which were always carefully manured? Were they in his own hands and at his own disposal, or were they let on long leases? To his mind the question was not one which could be settled either by the Government giving subsidies, or by the planters themselves. Did not it depend very much upon the dyers and upon the dyers' customers? and unless they were satisfied after full examination of the superiority of one class of indigo or the other, the contest would not be satisfactorily settled. There was another point. The planters, however well they might fare for the present, would have to be content at the end of two or three years with a new condition of affairs. As long as German factories were closed, well and good; but when they opened again at the end of two or three years, they would have on their hands an accumulation of stock, and was it likely they would hesitate to sell that at any loss in order to kill the renascent industry of natural indigo? Then there was another difficulty. He learnt that an important movement was on foot for securing for England the general aniline industry, including, of course, indigo, which was now in the hands of Germany, and it

was possible that the Government might assist. In that case the poor planter would not only have to contend with his foreign enemy, but he would find enemies among his own people in his own household. It would be a three-cornered duel, and the result was not easy to discern. So that altogether he could not say that the prospect three years hence was one which justified any very hopeful expectation; but he quite agreed that for the next two or three years any increase that could be put into the market of natural indigo would be certainly a paying proposition, and he only hoped that it might, as Dr. Perkin suggested, be the prelude to a bigger and better scientific agricultural system all round. In conclusion, he would be glad to hear any of the audience upon two points: one was the movement for capturing the aniline dye trade generally, and the other the consideration from the dyer's point of view as to the value in lasting effects of the two classes of indigo.

Mr. Donald N. Reid mentioned a method by which he obtained very much larger results from his lands than other planters. Instead of keeping his lands bare fallow, he used to grow indigo after the poppy crop was gathered, and within three months afterwards the indigo was manufactured. He also used the hot-water process and obtained good results. He noticed that those processes had been given up after he left the country.

Mr. T. Croysdale said he regarded the paper as somewhat of a funeral oration with regard to the cultivation of natural indigo. The suggestion was that owing to the present absence of synthetic indigo the cultivation of natural indigo might be resumed. He did not think, by the time that natural indigo came to this market, that it would obtain the present price, because it was most likely that by then synthetic indigo would again be flooding the market. Before the war began the price of natural indigo in Mincing Lane was about 2*s.* 6*d.* per lb. To-day it was 10*s.* per lb. He would be sorry for any planter who increased his cultivation in the hope of getting the latter price, as, before he could get his produce on to the market, synthetic indigo would again be in competition. With regard to the manufacture of synthetic indigo in the home market, the same thing applied very largely. It might be that synthetic indigo could be made in this country, but it would be very difficult for the Government to induce the public to subscribe three millions of money for the manufacture of synthetic indigo unless the public had some guarantee that they would be protected. If no protection was given, the first business of the German manufacturers after the war would be to undersell us and ruin the trade in this country. He believed that in the negotiations between the chemists and the Board of Trade the Government had made some sort of tentative offer for protection, but protection for a few years only was of no use. If the Government would guarantee protection for all time, then the British public would be able to subscribe money, and this country would not only be able to manufacture synthetic indigo, but the various aniline and alizarin dyes which were so largely consumed here.

Mr. S. G. Parsons stated that he had been selling indigo all his life, and he knew the planters and the buyers and the consumers. He did not consider the position of the planter was anything like so hopeless as Mr. Croysdale had tried to make out. No planter in his senses would ever expect to get the famine prices which at present obtained, but a planter could make a very handsome profit at prices of 3*s.* 6*d.* and 4*s.* per lb., and he (the speaker) did think planters would obtain reasonable prices for their indigo for some time to come. Again, if a duty was put on synthetic indigo coming from Germany, that would help the planter, because even if synthetic indigo was manufactured in this country it could never be sold at the same low prices that Germany sold it at, and if the price of synthetic indigo made in this country was, as he thought it very likely would be, 1*s.* per lb., instead of 6½*d.* charged by the Germans, that would give the planter a very much better basis on which to work. He thought planters could compete with synthetic indigo at 1*s.* per lb. and make a profit on their produce, but they could not compete with synthetic indigo at 6½*d.* per lb. Altogether, he did not agree that the outlook was so bad. One most valuable suggestion made by the author was that the planters, having now before them an exceptionally prosperous year, should put some of their profits towards a fund to improve their processes of manufacture, and to co-operate together for the benefit of the industry. Hitherto, the great fault of the planters had been that they had failed to co-operate.

Sir William Duke, K.C.I.E., C.S.I., in moving a hearty vote of thanks to the reader for his interesting paper, said there was a very wide divergence of opinion as to the future prospects of the Indian indigo industry. He thought, however, there was every prospect, for a year or two, that the planter would get a very good return from whatever he could produce from his present plant, and the land which he had at his immediate disposal. It must be borne in mind that if a planter was asked to go to further capital expenditure, to take up more land and put down more plant, he must have some definite prospects for some time to come, not merely for a year or two, but say nine or ten years. Dr. Perkin had emphasised the fact that much might be done in trying to improve the processes of manufacture with a view to getting a better indigo product. That was where perhaps least had yet been done. Something also should be done to obtain a better agricultural outturn. More had been done there, because that was a part

of the subject in which Government had particularly assisted. But when all was obtained that could be got by agricultural improvement, and when from the agricultural outturn everything humanly possible had been done in the way of an improved chemical output, he took it that we should still be working within very strictly defined limits—he meant that the agricultural outturn could not possibly be increased beyond a certain percentage, while the possible increase of the chemical output from that agricultural outturn must be similarly limited. The question was whether, with such improvements as could be obtained, the natural product would be able to compete with the synthetic product, supposing that the conditions which had prevailed up to the time of the war would be restored after the war. Possibly the planter could be satisfied that his outturn could be so improved that he could compete with the synthetic product as it was immediately before the war, but the question was, Was the synthetic product being sold at the lowest possible limit before the war? Was it not possible that the process of manufacture would be cheapened, and that, even supposing the planter grew two lbs. now where he grew one lb. before, the synthetic indigo manufacturer would still outsell him? In other words, was it not possible that whereas before the war Germany sold at a price of 6½*d.* per lb. she would after the war sell at 3*d.* per lb.? In that case, what would the chances be for the grower of natural indigo?

SIR EVAN JAMES, K.C.I.E., C.S.I., in seconding the vote of thanks, thought the Society was to be congratulated on having brought before an Anglo-Indian audience a paper giving such valuable and interesting information on a subject which was really of pressing importance. He hoped that synthetic indigo would be manufactured in this country, but he doubted whether the Government would protect it against foreign competition after the end of the war. Meanwhile, he hoped the planters in Bengal would try and make all the hay they could while the sun was shining.

The vote of thanks was carried unanimously, and the meeting terminated.

MR. A. WYNTER ROBERTS writes: The few surviving East India indigo planters who have had the temerity to persevere, under cruel conditions, in cultivating this beautiful and permanent dye—of which there are examples on fabrics woven thousands of years ago—are for once to be rewarded for their labours; not to anything approaching the full extent they would have been under free trade (the Government having prohibited the export from this country and from India except to this country, thus closing the door to keen competition from other countries), but it is to be hoped at least sufficiently to compensate them for losses sustained during a series of lean years. I recall meeting the late Mr. Henry Hudson entering the docks, probably for the last time, to look at the samples of several parcels of his mark, and the determination with which he said, "We (the planters) mean to go on." It is to be hoped that others will be equally resolute. Those who have spent the greater part of their lives in India cultivating indigo, and others in this country who have dealt with its distribution, still take a sentimental, as well as commercial, interest in what was a great industry. The decline, or practical ruin, was of course primarily due to the introduction of synthetic. Chemists say the latter is indigo. Should they not rather say synthetic indigotin, or anæmic indigo? If equal to natural indigo, why do some of our dyers, who produce the best work, adhere to the latter, and the Eastern races, whose carpets and fabrics last for generations, use natural indigo only, and why, if the two are identical, do dyers use natural in combination with synthetic? Good judges among the dyers differentiate between strong and weak indigo, yet the latter more than frequently yields the higher test. The system of buying and selling on test is modern, and its introduction led not only to injury to planters, but to misrepresentation, bribery and fraud, and, it has even been suggested, paved the way to make a market for synthetic. Analysis seems merely to have determined the percentage of indigotin. A vat made from Lower Bengal indigo, say a good J. & R. W. (Watsons' estates and factories producing this mark have long ceased to exist), testing 58 per cent. or 60 per cent., would last out a fine Tirhoot indigo testing 72 per cent. And a fine Java—almost pure indigotin—would be thrown away in a vat. But synthetic is stated to be equal to natural for piece dyeing, and has, of course, come to stay as a most important dyestuff. It is therefore misleading to talk of resuscitating the natural indigo industry if that is intended to imply anything like its former proportions. But so long as vegetable indigo can be supplied, even at considerably above the price to which it was driven by the introduction of synthetic on its merits, and by discreditable methods which have to some extent been exposed, it is highly improbable that the demand for indigo will die out. On the contrary, there were evidences of some increase in consumption, and values had actually advanced about 20 per cent. on the prices obtained by planters for last season's crop before the outbreak of, and consequently quite independently of, the war. The prevailing idea, except among those who are in actual touch with the trade, appears to be that indigo is dependent upon being able to compete in price with synthetic. If it were so, indigo could not stand. But if the production of indigo ceased, consumers of synthetic would receive a rude awakening—that is, if the latter trade were in German hands. Indigo has to some extent been driven out of production by undue depreciation in values, by some planters having to work with money borrowed at high interest, by

their produce being mercilessly sold in Calcutta at prices which would cover the advances, and by the system of buying arising out of "the combines," amounting practically to a "knock-out." Consumption would not have fallen off to the extent it has had qualities required for some markets been obtainable, for which buyers would willingly have paid extreme prices. Of late years I have been through many "Indigo shows," that is, samples of all the chests to be submitted for public sale, and have seen hardly a parcel suitable for Russia, very few for the Turkish markets, and sometimes not a single chest for Greece. This tends to show that buyers knew their business better than we or chemists could teach them, and that the various colours other than indigotin, and mineral matters, form the backbone and superiority of natural indigo. If it were not so the German chemists would not have expended fruitless efforts to fathom the mystery. Chemists attach possibly too much importance to purity and uniformity (synthetic for the trade is reduced from nearly pure indigotin to 20 per cent. paste). Before the days of the combines, all the private firms of dyers were in competition, and the making and maintaining of a vat was an art. To-day, active competition having ceased, the desideratum seems to be to reduce the process of dyeing so that "a child can do it." This may suit the proprietors (shareholders in the combines), who must be thankful if they get a dividend at all, but as many of the businesses absorbed by the combines yielded fortunes while in private hands, it should be an incentive to manufacturers and private dyers to take up the work in earnest. The policeman was said to be the best-dressed man in the City, and it is regrettable that the clause stipulating that natural indigo only should be used in dyeing the uniforms has been recently deleted from the contract. As the uniforms did not appear to have deteriorated, I asked one man, standing out in drenching rain, if his were a this year's cape? "This," he said; "why I have had it for five years!" I was advised by a clothing contractor, "while synthetic could be grown (!) at the present price, not to waste any time over natural indigo." Sailors in the Navy used to make their own clothes and paid a long price for the cloth, but all the alternate saturation with sea-water and drying in the sun made no impression on the colour. I believe that naval officers' uniforms and great-coats are still dyed with natural indigo, the result being that the clothing not only retains its natural colour but the staple is richer and fuller. The senior partner of a great firm of manufacturers in Lancashire, who used to buy five thousand pounds worth of indigo or more at a time, told me, after having practically given up using it, that he was positively ashamed of some of the goods that went out of his works, but the demand was all for cheapness. Much time and money have been spent, ostensibly on improving the quality and increasing the quantity of indigo obtained from the plant, but it appears that the latter can only be effected at the expense of the former. With the exception of Schrottkhi's first process (whatever it was), I have never seen anything approaching, much less improving upon, the qualities of the outturns of many years ago when the crops were at their largest, whilst the produce of some factories, previously of high repute, has been simply ruined by experimenting. The suggestion that at the end of the war the German company might have large stocks, and in order to compete against works established in the United Kingdom might reduce their price of 20 per cent. paste from about 6½*d*., at which it stood at the outbreak of the war, to 3*d*. per lb. is improbable. It is doubtful if there will be accumulated stocks, as, owing to the call to arms, there cannot be the supply of labour to carry on manufacture; also the large quantities of raw material formerly taken from this country are not available. Great Britain has only taken a small portion of their output; and, with the exception of Austria and our Colonies, their exports may be as usual, if they can continue to produce. It is not generally known at what price synthetic can be sold profitably. A German merchant in London, doing a large export trade in natural indigo, being a considerable shareholder in the German company, tried to ascertain, but was told to take his dividends and ask no questions. It is said to have cost a million to introduce, and may be carried on at the expense of other departments. The proposed company to be formed in this country under the auspices of the Government, for the manufacture of aniline and synthetic dyes, is taking definite shape. One of the difficulties which has hitherto stood in the way of developing this industry has been the duty on alcohol. By its exemption it is to be hoped our manufacturers will be able to produce the colours on as good terms as the Germans have in the past, not only for our home trade and Colonies, but for our friends abroad. While rendering such valuable aid to the synthetic and aniline industry by financial support and favourable conditions, it would be a great boon to the indigo planters, and benefit many of our fellow-subjects in India, if the Government would also assist the natural indigo industry. Financial help to planters requiring it during the growing and manufacturing seasons would no doubt lead to increased cultivation; but if there were a clause in all Government contracts stipulating that only natural indigo of British origin should be the blue dye used for all their departments, it would give the planters heart, and certainly lead to an increase of consumption for private, or rather public purposes, without injuring the enormous trade which must come in artificial dyes. Let us have "All British" certainly for Government work, but ungrudgingly including and encouraging Central American indigo for general purposes, as that product, known in the trade as "Guatemala," was a good second to "East India" in the old days, and still comes to this market

on a small scale, much of it of desirable qualities, and never disturbed by new processes. In the interests of planters there is room for a complete revision of the system of disposing of their crops in London.

MR. WILFRID MATHIESON writes: It seems to me that, in order to give the Indian indigo industry encouragement, an Act of Parliament might be passed during the war, as soon as possible, which would make the use of the word "indigo" illegal as describing any substance except the product of the indigo plant, or the use of the word in connection with any material, fabric or other thing except it be dyed with natural indigo. It is illegal to sell margarine as butter, and it should be illegal to sell the product of the laboratory by a name which should be strictly reserved to the natural product. It ought not to be difficult for the "kultured" German to invent a name for what is called synthetic indigo, as dissimilar to indigo as margarine, as a word, is different from butter, or Dutch metal from gold.

CANTOR LECTURES.

THE HISTORY AND PRACTICE OF THE ART OF PRINTING.

By R. A. PEDDIE,
Librarian, St. Bride Foundation Typographical Library.

Lecture II.—Delivered November 30th, 1914.

THE EARLY NINETEENTH CENTURY.

It is curious to reflect that in the year 1800, at least 350 years after the invention of printing, the art had developed so little mechanically that a fifteenth-century printer would have found himself quite at home in a printing office of the last year of the eighteenth century. He would have found the same wooden press, with perhaps some slight additions of metal screws and levers, which would be quite clear to his mind after one trial. He would see the same kind of inking balls used, and he would note that the paper, although of a quality not up to his standard for book printing, was produced in the same manner as in his own day. The type would perhaps appear to him better finished than that he recollected. But in all essentials the printing office of 1800 was the printing office of 300 years before. Everything we know to-day in the art has come into use since 1800.

The printed sheet of to-day is printed on machine-made paper. It is either set by a machine or set with machine-made type. It is either printed from this type or stereotyped by machinery. The press is a power press, and the resulting printed sheets are sewn, glued, and bound by machinery. My task now is to trace the development of the machine industry of to-day from the handicraft of the earlier period.

The three great inventions which made the present machine production possible were the paper-making machine, invented by the Brothers Fourdrinier in 1803; the printing machine, invented by Koenig in 1811; and photography, invented by Daguerre and Fox Talbot in 1839.*

Previous to these, however, an improvement which amounted to an invention had been made in the press by Charles, 3rd Earl Stanhope. The great change he introduced was to substitute iron for wood in the frame of the press, and add multiplying levers between the bar and the platen so that the work of the pressman was much reduced. William Morris was wont to say that this substitution of iron for wood was the only improvement that had been made in the art, and when we consider the enormous gain in rigidity we can understand what Morris meant. The power press did not exist for him, but he wanted the best possible effect from the hand press. The story of the hand press and its development after this date is an engineering one. Better castings, finer fitting, still more rigidity, and the proving press used to-day by photo-engravers produces those really wonderful proofs which their customers vainly try to emulate.

PAPER.

The paper-making machine invented in 1803 was in most of its essentials the paper-making machine of to-day. Up to this date all paper was made in single sheets by hand. The pulp was put into the mould by the workmen, and then the mould was shaken to distribute the pulp evenly, and the resulting sheet removed for drying and pressing. The principle of the invention was to substitute endless woven wire sheets for the mould, and as the paper was formed by the felting of the fibres to lead it between heated cylinders to dry and press it. As it came from the machine the paper was cut into sheets of the standard sizes. The continuous web of paper was being made in 1803, but it was not to be used as a web for rotary printing until 1868.

PRINTING MACHINERY.

The next great invention which attracts the notice of the student is the development of the printing press into a machine.

* The last date must be read in conjunction with the remarks on the history of photo-engraving in Lecture III.

The three principles of printing machinery are, first, the platen action in which the pressure is applied by one flat surface acting on another. This was the hand-press method. Then follows the cylinder, round which the paper is led, rolling over the flat bed on which the type is placed. The third principle is the rotary method, where both type and paper are placed on cylinders geared together. Of the two latter the third was the the first to be invented, but the last to be used. William Nicholson, in 1790, took out a patent for a rotary printing machine which, however, was never made for use. He also specified a flat bed cylinder machine similar in action as regards position of type and paper to the later invention of Koenig. But no really practical methods of using them were added to either of these inventions.

Before we come to the cylinder machines we must deal with the attempts to apply power to the hand press. Frederick Koenig in 1803, at Suhl, attempted this. He substituted leather rollers for the inking balls, and introduced mechanism to take the carriage under the inking rollers and then under the platen. Koenig came to London and succeeded in inducing Bensley, Woodfall and Taylor to finance him in his experiments. By 1810 he took out a patent, and in April 1811 he printed sig. H of the "Annual Register." This was a modification of Koenig's first attempt to apply power to the old form of press, and was patented by him in England in 1810.

The next year, 1811, he took out another patent, this time for the machine which was to be the parent of all flat bed cylinder machines from that day.

John Walter, of the *Times*, ordered two machines after seeing the new cylinder machine, and presumably after hearing Koenig's ideas for the future. The issue of the *Times* for November 29th, 1814, was printed entirely by steam power. Mr. John Walter's own account of the innovation is interesting:—

"Our journal of this day presents to the public the practical results of the greatest improvement connected with printing since the discovery of the art itself.

"The reader of this paragraph now holds in his hands one of the many thousand impressions of the *Times* newspaper which were taken off last night by a mechanical apparatus. A system of machinery, almost organic, has been devised and arranged, which, while it relieves the human frame from its most laborious efforts in printing, far exceeds all human powers in rapidity and despatch. That the magnitude of the invention may be justly appreciated by its efforts, we may inform the public that after the letters are placed by the compositors, and inclosed in what is called the 'forme,' little more remains for man to do than to attend upon and watch this unconscious agent in its operations. This machine is then merely supplied with paper, itself places the forme, inks it, adjusts the paper to the newly inked type, stamps the sheet, and gives it forth to the hands of the attendant, at the same time withdrawing the forme for a fresh coat of ink, which itself again distributes to the ensuing sheet, now advancing for impression; and the whole of these complicated acts is performed with such a velocity and simultaneousness of movement that no less than 1,100 are impressed in one hour."—The *Times*, November 29th, 1814.

I have said that some time after April, 1810 Koenig gave up entirely the idea of the modification of the screw press, and became a convert to the cylinder principle. It is alleged, with some background of justification, that Koenig borrowed the idea from Nicholson's patent of 1790. He certainly met Nicholson, who helped him to prepare his patents.

One other type of machine, constructed during the period ending 1814, remains to be mentioned. The printer of the *Norwich Mercury*, Mr. R. M. Bacon, together with Bryan Donkin, designed a machine in which the types were arranged and fixed on a revolving four-sided prism. The ink was applied by one roller, which rose and fell to meet the irregularities of the prism.

This patent, No. 3757 of 1813, contains the first reference to composition rollers, without which rapid machine printing would have been impracticable.

After Nicholson's, this was the first rotary machine as against the flat bed cylinder machines of Koenig.

It is difficult to say when Bacon and Donkin's machine was first used. The *European Magazine* for January, 1815, claims the invention for them as against Koenig, and goes on to state that another inventor had produced a printing machine at Plymouth "about ten years since, which has been and still is used by a tradesman there for printing his bills."

Koenig's final effort in this country was to transform his *Times* machine, which printed on one side only, into one that perfected the sheet or printed it on both sides

during the progress of the paper through the machine.

His patent for this is dated 1814. One large machine of this sort was made for Bensley in 1815, but it was too heavy and expensive, and this was the only one made. It produced 750 perfected sheets per hour, or 1,500 impressions.

Koenig finally left England in 1817, and started the firm of Koenig and Bauer at Kloster Oberzell, where it still flourishes.

The invention was now accomplished, machine printing was a fact, and although the hand press still held its own it must have felt the beginning of the severe competition.

We have followed the development of the flat bed cylinder machine for newspaper purposes to 1814. The machines then built by Koenig for the *Times* were used until 1827 (by 1824 they were printing 2,000 per hour), although Applegath and Cowper, who had succeeded Koenig at the *Times*, had modified them considerably.

In 1827 they built a new machine still printing on one side only, but raising the rate of impressions to between 4,000 and 5,000 per hour.

Perfecting had been abandoned. As Cowper says, "The principal object in a news machine is to obtain a great number of impressions from the same forme on one side of the sheet, and not from two formes on both sides as in books. This machine required eight attendants, four to lay on and four to take off. These machines were used by the *Times* until 1848, when the flat bed principle was finally abandoned.

The failure of Koenig's 1815 machine, for perfecting was not the end of perfecters. Applegath and Cowper turned their attention to this type of machine and considerably improved it. With little alteration it developed into the perfecter of recent times.

Up to 1850 the job or book printer was content to use the hand press and the power platen machine, and the big houses used the perfecters mentioned above. Here and there, of course, various experimental cylinder machines were used.

The invention by Main in 1850 of his cylinder machine formed the first step in the sequence of Wharfedale type machines. His cylinder did not rotate fully, but after making three-quarters of a revolution reversed itself and at the same time was raised to clear the type carriage on its return journey. The bed also had a new drive, being a crank with multiplying gear attached.

In 1848 news and book printing machines parted company. Applegath in that year introduced once more the rotary principle. The failures of Nicholson in 1790, and Bacon and Donkin in 1813, were at last avenged, and rotary printing has been the method for printing newspapers ever since that date. He placed a great cylinder with its axis vertical, and with as many faces as there were columns to be printed. The type was held by wedge-shaped rules, and as many feeders were arranged round the machine as the space permitted. The next improvement was the Hoe machine, where the axis of the main cylinder was horizontal and the type held by a special device known as the Turtle. These Hoe machines in this form lasted until 1868, when the final great invention in newspaper printing was introduced and the Walter press was set up.

Printing Types.

Turning to the types of this early part of the nineteenth century, as Mr. Talbot Baines Reed said, Bodoni and Didot killed the old style and left the modern Roman. But the new Roman had hardly established itself when a demand for fat face type arose. All the founders supplied the demand, and the specimen books of this period are full of types with these broad faces. The usual reaction set in, and from an attempt to condense type after the French fashion arose the Scotch letter. The English founders, however, retained the rounder forms of letters. The period about 1820 was noted for good printing, but the Roman type used was not as legible as the old style. Hansard said, in 1825, "the specimen of a British letter-founder is a heterogeneous compound made up of fat faces and lean faces, wide set and close set, proportioned and disproportioned." This style was maintained with some slight improvement as regards book faces until the forties.

For this period one is always told to refer to the Chiswick Press for the best printing, and the books issued by Pickering are generally referred to. The work of Charles Whittingham the elder, the founder of the Chiswick Press, possesses few claims to distinction. It was his nephew who founded the press at Took's Court, and to whom his uncle left the Chiswick Press. He it was who printed books for Pickering which have always been looked upon as excellent work. Corrall, who printed most of the Diamond Classics for the same publisher, also did good work, and here it was, no doubt, the publisher who was responsible for the excellence

of the volumes. Pickering was an artist in book production, and the simplicity and dignity of his publications had a great influence on the work of his time.

The combination of Pickering and the younger Whittingham produced most excellent results in later years; in fact, until the death of the former in 1854.

In 1844 Caslon's were asked to supply type for a Juvenal to be printed for Pickering in old-faced Roman. Caslon's discovered the old punches of the original Caslon's Roman type, from which a fount was cast. The Juvenal not being ready, the type was used for Lady Willoughby's Diary, published by Messrs. Longman in 1844, and at once the old face type became popular, and began to oust the compressed and fat face varieties. Some people, however, considered it somewhat too archaic, and Messrs. Miller & Richard began cutting a series of revived old style faces. They were followed by the other founders, and from about 1850 the better class of book work has been in one or other of these types.

Engraving and Illustration.

I have now to deal with the methods of illustration and engraving.

Bewick's development of illustration on wood gave an impetus to the art which lasted until the rise of the photographic reproduction processes in the middle 'eighties. It did not preserve the high character which Bewick gave it, but gradually degenerated into a trade. There was a slight revival, artistically speaking, about 1835, but the effect of this soon passed. Artisans had taken the place of artists.

Woodcuts, of course, could be printed at the same time as the text, and the whole history of illustration during the nineteenth century is a search after a process which would mechanically produce from pictures or drawings blocks which could be printed in the same way.

The invention of photography in 1839 led to no immediate result in this direction, although Fox Talbot and others thought and experimented much on the subject. However, the early history of the development of photographic engraving is dealt with in the next lecture. The period under discussion does not contain any real commercial development in this direction.

Lithography had been invented by J. A. Senefelder in two forms: engraving on stone in 1796, and the chemical method or true lithography in 1798. It is unnecessary to go into the history of this art, as Mr. Pennell has so recently and so elaborately explained it to you. It was brought to England in 1800, and gradually attained popularity. Its use for book illustration was not very frequent, as it necessitated two printings on different machines; and it was, therefore, not a formidable rival to wood engraving.

Occasional books occur with illustrations printed by unknown processes, such as acrography, which was probably a method of surface printing etchings.

Colour printing during the first half of the nineteenth century was almost entirely of an experimental character. Always there was the attempt to get a colour process that could be printed in the ordinary press or machine. Savage developed wood-block colour printing to an extent hitherto unknown, but with no commercial results. Baxter, of course, was the great colour printer of the period, and his work was special to himself. His delicacy of treatment and wonderful eye for colour, together with a patience that must have been almost superhuman, places his work in a different category from any other. It was a personality, not a process.

This hurried survey of a period roughly corresponding to the first half of the nineteenth century leaves printing at a point when it had definitely developed from the handicraft of 1800 into the machine industry. With machine-made paper and machine printing, it only wanted one thing to complete it--mechanical illustration. By this time it was well on the way, and the principal topic of my next lecture will be this final development.

THE OCCURRENCE OF ASPHALT IN THE STATE OF OKLAHOMA.

By Chas. N. Gould, Ph.D.

The asphalt deposits of the State of Oklahoma are among the most extensive in the United States. The majority of the known deposits occur in the southern part of the State. The greater part of the asphalt in Oklahoma is in the form of rock asphalt; in other words, it is rock impregnated with asphalt. In several cases, however, the material occurs in an almost pure, semi-viscous state. In other instances it is mined as a black, hard, and brittle substance known as grahamite, gilsonite, or impsonite, having the general texture and appearance of anthracite coal.

Pure asphalt or bitumen is derived from the natural or artificial distillation of petroleum. It is the last distillation product, the part that remains behind after all of the volatile oils and gases have

been distilled away. In many parts of the world, notably on the island of Trinidad, semi-liquid asphalt comes to the surface in great quantities and spreads out, forming a so-called lake. The evaporation on the surface forms a hard crust, but beneath the crust the asphalt is soft and viscous.

There are four chief modes of occurrence of asphalt as found in Oklahoma: first, as beds or sheets of pure asphalt interstratified between shales and sandstones; second, as impregnations of rock along fault lines; third, as impregnations of rock in regions of stratified rocks, vertically inclined; fourth, as impregnations in regions of level-lying strata. These four modes of occurrence will be discussed briefly.

In a number of localities in the Ouachita Mountains, in south-eastern Oklahoma, asphalt occurs in the form of gilsonite, grahamite, or impsonite. The material has been deposited in beds or sheets usually inclined at high angles, interstratified between shales and clays of the Carboniferous age. These beds are lenticular, sometimes as much as 20 ft. in thickness and occupying an area of several hundred feet in diameter. Frequently a series of these lenticular beds occurs in the same general region.

The material derived from those beds is black, hard, and brittle, breaking with a conchoidal fracture, having the general appearance of anthracite coal. The most extensive deposits so far discovered in Oklahoma are at the Jumbo Mine, in north-western Pushmataha County, and at Bunchtown, west of Tuskahoma. Deposits are known to exist at Page, in LeFlore County.

Much of the asphalt in Oklahoma occurs along fault lines, where the rocks have slipped up on one side and down on the other. At some unknown depth the faults or fissures have intersected beds carrying petroleum. This oil, being volatile and tending to escape to the surface, has travelled upward along the fault line. The lighter oils and gases have long since escaped into the atmosphere, while the heavier asphalt has remained behind and has impregnated the rocks on either side of the fissure. If the rock alongside the fissure happens to be a limestone the substance is called lime asphalt; if it is a sandstone, the material is a sand asphalt. So it will often happen that a bed of lime asphalt occurs beside a bed of sand asphalt, or *vice versâ*, the two beds being on opposite sides of the fault line.

The thickness of the so-called veins on either side of the fault lines varies from two or three feet to more than fifty feet. Usually the sandstone, which is the more porous rock, has been filled to a greater distance from the fissure than has the more impervious shale and limestone. The faults often extend along the surface for a distance of several miles. The depth to which the fissures extend is unknown, but in some cases, as shown by drilling, it is at least 1,000 ft. These faults are most abundant in the Arbuckle Mountains, in Murray, Johnston, and Pontotoc Counties.

There are several regions in southern Oklahoma, particularly in Carter, Atoka, Pushmataha, and LeFlore Counties, where the rocks have been tilted on edge, and afterwards truncated, leaving the upturned edges exposed on the surface. These rocks consist largely of alternating layers of shale and sandstone. Many of the sandstones are known to contain asphalt. These ledges vary in thickness up to 100 ft., and in many cases the greater part of this thickness of sandstone has been impregnated with asphalt. In a number of cases this material has been mined and utilised for road building, street paving, and other purposes.

Throughout many parts of the State asphalt occurs in rocks which lie approximately level. At least three separate regions in the State contain deposits of this character.

In a number of the southern counties of Oklahoma there are certain deposits of Cretaceous age, which lie level or dip at low angles to the south. The basal member of the Cretaceous, known as the Trinity sand, is a formation several hundred feet thick, composed chiefly of loosely-consolidated sands. Immediately above the Trinity is a limestone, also of Cretaceous age, known as the Goodland limestone. In many localities asphalt occurs in the rock at the top of the Trinity sands, and immediately below the Goodland limestone. Deposits of this kind occur near Tishomingo, Bennington, and Bokhoma.

Asphalt occurs in level-lying rocks in several counties lying south and west of the Arbuckle Mountains, and in the region surrounding the Wichita Mountains. As here exposed it is contained in ledges of sandstone of Carboniferous age, which were formerly buried at considerable depths beneath the surface, and which, at that time, doubtless were oil sands. As the surface has been brought down by erosion, exposing the various sandstones containing the hydro-carbons, the lighter and more volatile of these substances have escaped, and have been dissipated into the air, leaving behind the involatile residue known as asphalt. Drilling in this general region reveals the presence of a number of ledges of sand, all the way down to 1,000 ft., all of which contain considerable amounts of oil and gas. The Healdton, Loco, Lawton, Duncan, and Gotebo oil and gas fields, in south-western Oklahoma, are located in regions where conditions are as outlined above.

A third region in Oklahoma where asphalt occurs, in rocks lying approximately level, is in the north-eastern part of the State, where the oil sands of the Mid-Continent field outcrop on the surface. There is a region west of the Grand River, extending from the Arkansas River north to the Kansas line, containing numerous deposits of asphalt and oil seeps and springs. This material escapes from certain sandstone ledges, Carboniferous in age, which are carried beneath the surface by the western dip of the rocks, and which, when penetrated by the drill at points twenty to one hundred miles west and south-west of

the outcrop, produce large quantities of oil and gas.

Analyses of the rock asphalts of Oklahoma show that the composition of the material varies considerably. The so-called lime asphalt contains all the way from 2 to 10 per cent. bitumen, the remainder being calcium carbonate. The sand asphalt runs usually from 10 to 20 per cent. of bitumen, while the shale asphalt usually contains less than 5 per cent. of hydro-carbons.

Asphalt has been utilised to a limited extent for the manufacture of paints, varnishes, and roofing; also quite extensively for street paving and road making. It has been demonstrated that a mixture of the lime and sand asphalt makes the best paving.

The amount of the material available in Oklahoma is practically inexhaustible, but only a relatively small amount has been utilised.

THE BRITISH IN BUSRAH.

The capture of Busrah within seventeen days of the declaration of war on Turkey solves the question of the sovereignty of a port of great importance to Great Britain's commerce in the East. As the chief port of Baghdad it has long possessed value in the eyes of all, whether Europeans or Turks, interested in the trade of Mesopotamia and contiguous regions. In the middle of the eighteenth century the East India Company established an English factory there, and even now considerable trade is carried on with Hindostan, while trade with the interior is maintained by means of caravans to Aleppo and Baghdad, whence goods are conveyed to Constantinople. The Turkish domination dates from 1660, but since that time Busrah has passed through many vicissitudes, passing into the hands of the Persians in 1777, and for a year or two after into those of the Montefik Arabs, who occupy the desert to the south-west. The political position of Busrah is of some considerable importance, especially because it will in all probability form the terminus of the Baghdad railway, and perhaps also the eastern objective of the proposed trans-Arabian railway from Port Said to the Persian Gulf. The town is unhealthy, and most of the Europeans reside at Maghil, which has been built on a less fever-stricken site. The adjoining country is fertile, and wheat, rice, barley and dates of varied and excellent quality, besides fruit, such as apricots, apples, figs, olives, pomegranates and grapes, and vegetables, are cultivated in great quantities. There are also extensive fields of roses, raised for the manufacture of attar. Some eight months ago a series of outrages had been perpetrated on British subjects, culminating in the murder of the captain of a British steamer plying on the Shat-el-Arab. Had the Turkish authorities grappled earnestly with the situation the Arab agitators and other lawless elements might have been restrained, but no genuine regret was shown by the Turks, and since the outbreak of the war the Germans have done all they can to strengthen the footing that the agreement to locate the terminus of the Baghdad railway at Busrah had given them. The loss of the town is, therefore, a blow to both Berlin and Constantinople, and the fact that the victors are an Indian force adds to the prestige of the Government of India in a region where British-Indian commercial interests particularly require watching and support. Apart from the Baghdad railway, Busrah is the contemplated terminus of the trans-Arabian line, as already mentioned, and our influence over Kowcit, the alternative port at the head of the Persian Gulf, would be a great assistance in the expansion of trade in this important region.

Since the beginning of 1914 the trade in petroleum has developed, the Anglo-Persian Oil Company having maintained a strong hold on the local market, and gained immediate popularity in respect of price and quality. During 1913 twenty German steamers of the Hamburg-America Line called at Busrah, and German returns gave the value of imports for Busrah and Baghdad at close on £2,000,000, as compared with about half that sum in 1912. The imports included about 34,000 tons of material for the Baghdad railway, while the remainder consisted chiefly of sugar, haberdashery, liquor, beer and spirits, steel and brassware, soap, paperware, glass and matches, as well as cement and lime for building purposes. The still more recent capture by the British of Kurna is a welcome reply to the closure by the Turks of that port to all foreign shipping in 1913.

NAVAL CONSTRUCTION IN EUROPE.

The *Rivista Marittima*, in a recent issue, gives the following statistics showing the activity displayed by the various belligerent Powers in the construction of warships at the present time.

The particulars relating to the British Navy should be too well known in this country to need reproduction here.

At the present time, France has 12 armoured ships in construction, of which 3, viz., "La Bretagne," "La Provence," and "La Lorraine" (of 23,500 tons displacement), will be ready for sea early this year; 5, "La Normandie," "La Gascogne," "La Flandre," "La Languedoc," and "La Bearn" (of 25,200 tons each), are already launched, and will be completed in 1916; 4, "La Duguesne," "La Tourville," "La Lyon," and "La Lille" (of 29,500 tons each), will be launched in about two years' time, and ready for sea in 1917.

In addition to these, there are 3 cruisers (of 4,500 tons) which will be launched this year, and completed by 1916; 5 torpedo-destroyers, of which 3 will be ready this year; 22 submarines, 10 of which are almost completed, and 8 will be ready during the course of the present year.

France has sixteen Government dockyards and eight private yards where these vessels are being constructed.

Russia has 12 armoured ships in construction: 4 of these (of 23,400 tons each) have already been launched, and will be completed this year; 4 others (of 22,900 tons), also launched, will be ready for sea in 1916; whilst the remaining 4 (of 32,400 tons), still on the stocks, will be completed by the same period.

Besides these, she has 8 cruisers (of 7,000 tons displacement), which will be ready in 1916. She has also 8 cruisers (of 7,000 tons each), which will be ready in 1916; 49 torpedo-destroyers, of which 24 will be completed this year, and 25 others in hand; also 25 submarines, 15 of which number will be ready this year.

Russia has sixteen Government dockyards and sixteen private yards.

On the other side, 7 armoured ships are being built for the German Navy, 3 of which (of 27,000 tons) will be completed in 1916; while 2, viz., the "Kronprinz" (of 25,800 tons) and the "Lützow" (of 26,500 tons), have both been launched, and probably will be ready for sea this year. Of the other 2, no particulars are given. Besides these, 17 torpedo-destroyers and 7 submarines are in construction, and will probably be ready for sea in the course of the next twelve months.

Germany has five Government and ten private yards for the construction of her warships.

In the Austro-Hungarian empire, which possesses only one Government dockyard and eight private ship-building establishments, 3 armoured cruisers are in hand, one of which, the "Szent Isvan" (of 20,500 tons displacement), is nearly ready for sea, and the other 2 will probably not be completed till 1917. In addition, 3 cruisers, 2 of which, it is stated, are nearly ready, 6 torpedo-destroyers, 27 torpedo-boats, and 5 submarines complete the list of vessels now in hand in that country.

BELGIAN INTENSIVE CULTURE.

The *Times* announces that agricultural experts among the Belgian exiles in England have offered to disclose the secrets of their highly successful system of intensive culture for the benefit of British small-holders. The suggestion came from the Queen of the Belgians, who thought that the instruction might be accepted as a token of the gratitude of the Belgians for the refuge and hospitality they have found here in their dire distress. The Belgian Government have approved the scheme. They are naturally anxious that no undertakings should be entered into by their people which would ultimately hinder their repatriation when the time comes for their return to Belgium, but they are of opinion that that objection does not apply to experiments in intensive culture in this country.

Accordingly a committee has been formed to carry out the scheme. The chairman is Sir Richard Paget, 9, King's Bench Walk, Temple. It includes Lord Milner, Lord Grey, Sir Horace Plunkett, Lady Lugard, Lady Lovelace, Lady St. Helier, Mr. Christopher Turnor, Sir Robert Turnbull, Mr. Cecil Harmsworth, M.P., Mr. Prothero, M.P., and several other representatives of agricultural, small-holdings, town-planning, rural housing, and co-operative associations. The committee propose to form themselves into a non-profit society to be called the Belgian Organisation Society.

It is proposed that the agricultural refugees should be found temporary employment on general agricultural work, such as reclaiming waste and cleaning foul lands, so as to prepare these for intensive cultivation, and that as soon as possible a selection should be made of those families who have had a thorough experience in the working of the Belgian system to give local demonstrations, or set up agricultural settlements on co-operative lines. The Belgian Government have given to the committee the services of a number of their official experts in market-gardening, the rearing of poultry, and the planting and cultivation of trees, and have promised that these services will be continued until the scheme is placed on a practical working basis. The committee have in turn invited the assistance and co-operation of the county councils and the agricultural colleges. It is also proposed to add to the settlements a certain number of British small-holders, who will learn the system and carry on the work after the Belgians have gone home. On suitable soil the Belgians can grow as many as five successive crops in the year under glass. The necessary plant is of the simplest kind, being chiefly plain sheets of glass in rough wooden frames, which are made by the cultivators. The improvement of the soil is a special study with them. In fact the greater part of the soil of the Belgian market gardens has been made on waste and barren ground by the cultivators themselves.

The committee hope to get the funds for starting the scheme from two sources. The Board of Agriculture have suggested that they might apply to the Development Commissioners for grants for the local demonstrations of intensive culture, as the object is educational. As regards the housing of the families constituting the co-operative settlements, temporary accommodation will have at first to be found; but it is hoped that when the schemes have been started the means for providing permanent housing will be obtained under the provisions of the Housing (No. 2) Act.

THE INTRODUCTION OF AMERICAN COTTON INTO SIND PROVINCE, INDIA.*

The cultivation of cotton in Sind has extended considerably during the last few years, and the annual production is now about 150,000 bales. The Sindhi variety yields a short, coarse, strong cotton of good bright colour, which realises about

* Abstract of a paper read by G. S. Henderson, Deputy Director of Agriculture, Sind, at the Third International Congress of Tropical Agriculture.

5½d. per lb. with Middling American at 7·30d. per lb.; the ginning yield is about 33 per cent. The method of cultivation consists in sowing the cotton broadcast after irrigation, and ploughing it in; subsequently the crop receives no attention except one or two hoeings and occasional irrigation.

In attempting to improve the cotton of Sind, superior Indian varieties were first tried, but were soon discarded in favour of exotic kinds. The Department of Agriculture found that Egyptian cotton succeeded on the Government farms, and afterwards 4,000 acres were planted on the Jamrao Canal. The crop was of good quality, but was difficult to dispose of, as the Bombay mills do not use Egyptian cotton. Egyptian cotton has moreover the disadvantages that it requires more careful cultivation than Sindhi and has a long growing period, which practically restricts its growth at present to the Jamrao Canal area.

Some years ago trials were made with American cotton, and it was found that this had the advantages of having a short growing period (thus enabling it to be grown on the common inundation canals), of giving a yield per acre equal to that of the Sindhi cotton, of being hardy and amenable to the method of cultivation employed for the Sindhi variety, and of being more easily marketed than Egyptian cotton. The author, during a visit to the cotton-growing regions of the United States, selected the "Triumph" variety as being the most suitable for Sind. This plant bears large bolls, matures early, gives good yields, and is well adapted for growth on irrigated lands. After repeated experimental trials at the Government farms, it was decided to grow the variety on a large scale, and, early in 1913, 30 tons of seed were distributed in the Jamrao area and 10 tons in Sukkur and Upper Sind Frontier. A syndicate of Bombay millowners was formed to buy, gin, bale, and dispose of the crop derived from this seed. The crop amounted to 511 bales, and was sold in Liverpool at an average price of 1d. per lb. below that of Middling American.

Seed for planting 6,000 acres has been distributed this year (1914), and it is expected that with better ginning the product will be of equal grade to Middling American. A seed farm of 200 acres has been started by the Agricultural Department in order to prevent deterioration of the stock.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Reduced Imports.—The time would seem to have arrived at which the interference with foreign manufacturing arrangements should be leaving visible gaps for British manufacturers to fill. A glance at the import statistics does not destroy that impression. In the four months August–November, 1913, yarns and fabrics valued at £15·2 millions were imported into this country. The corresponding figures for 1914 are £6·5 millions, and it may be thoroughly believed that no reduction of expenditure or decrease in re-exports accounts for the full difference. After making certain allowances under these heads, a remainder exists representing trade which the English producer might transact. The visible opportunities are greater in some directions than others, although there is a remarkable resemblance between the amounts of the falls in the three principal classes of trade. In cottons, in the four months, imports have been £2·8 millions less, in woollens £2·5, and in silks £2·2 millions less. Closer discrimination is needed to bring out the position of the fully-manufactured classes, but as general evidence of the scope afforded in the home market these overhead figures may serve.

Natural Delays.—For several reasons the new opportunities created by a violent crisis do not make themselves perceptible all at once. Existing stocks of imported goods tide over their owners for a time. There is a universal ignorance as to what may happen next, and a doubt of what had best be done which clears only by degrees. The prevailing uncertainty powerfully affects goods known to be procurable upon request; much more those which are neither known to be wanted nor to be obtainable. If a few months slip by before all concerned become conscious of a new stir, the fact should not be surprising, although comment upon the absence of demand in replacement of foreign articles has been heard. Thus an English silk-spinner has been known to lament that nothing deserving of the slightest notice had happened to promote demand for spun silk yarn, although some £14 millions of various sorts of silk are imported with regularity. It is apparent that France and Switzerland have continued to furnish the English market with reduced but still considerable supplies, and it is to be supposed that before the English silk-spinner can derive appreciable benefit a sale of woven goods somewhat different in character from the imported sorts must be set in motion. The sale may be coming, but it has not yet definitely arrived.

Foreign Cottons and Woollens.—In the four months imports of cotton yarn, probably because of the occupation of Belgium, have been cut down from £206,000 to £48,000. Those of cotton piece goods and hosiery have been reduced from £819,000 to £326,000, and those of cotton lace from £682,000 to £238,000. The items are minute in the general perspective of cotton affairs, although the reduction is in a large enough proportion to be appreciable in some quarters. Still more tangible in practice should be the fall in imports of wool goods, a fall that means a change from £3·3 millions to only £826,000. In this line of business the absence of the foreign competitor is made noticeable chiefly by inquiries from merchants for cloths of the German and French type. The goods are woven from mule-spun yarns in contrast to the regular frame-spun British articles. Samples of fine German, Austrian and Belgian worsted coatings have been circulated by merchants, but these are of less consequence than the dress goods, of which

sixty million yards per annum have been imported into England latterly, and of which large sales are made also in other countries by Continental manufacturers. Wool dress goods of the kind chanced to be in first favour before the opening of the war, so that the desire to supply the market with fabrics of that class is particularly marked.

Differences of Machinery.—The quantity of machinery in this country available for spinning wool yarns required for dress goods of the Continental type is negligible. The machines are relatively expensive in themselves and in their housing, as they occupy large floor-space. It is thus not readily practicable to discard frames and instal mules, and there is no chance of this being done. Mills would require to be built for the purpose and workpeople to be found, and although no doubt exists of the profits to be picked up in the present, the future is uncertain. The experience of some owners of both types of machine is that the worsted frame has been more remunerative than the worsted mule. A sound yarn is made on the mule of greater fineness than can be made on the frame from fibre of the same length. The mule yarn is more supple, having less twist; and while each sort has its advantages, the balance of English opinion has favoured frame yarn as the more serviceable of the two in English conditions. The courageous course of erecting new mills is open to those who choose to adopt it. Short of that course, the choice lies between finding new employment for frame-spun yarns or utilising existing machinery to duplicate mule yarn as nearly as is possible.

Imitation Yarns.—In several directions ingenuity is hard at work to provide wool yarns of the Continental character with the aid of existing machines. A signal success that has been scored in one quarter is understood to be due to the employment of wool of a particular class, and to the use of worsted and cotton machinery in combination. Wool and cotton in the form of rovings are placed upon the cotton mule, and are spun into a mixed wool and cotton yarn that is almost indistinguishable in its main characteristics from an all-worsted yarn spun upon the mule without oil. The article imitates what is called in the trade "French dry-spun," and a great demand has sprung up for the product. This development may easily prove the starting-point of a large manufacture of cloths at a popular price and of the softness and fullness desired. The result of other efforts is awaited, and it is not too much to expect that they will go some way towards the goal, even if the outcome is something that is neither Continental nor English, but midway between these types. After trade openings have been made and been noticed, a time necessarily elapses before all the technical problems that are involved in making goods of a new type can be satisfactorily worked out. The influences of fashion and of season enter into the case, and for all reasons the suspension of competition may be counted on to produce larger effects than have been felt hitherto.

Mercerising in Acid. Over forty years passed before John Mercer's patent of 1850, for the action of alkalies upon vegetable fibres, was exploited with the object of improving the lustre of cotton yarn. Once afoot, the new process of mercerising extended rapidly, and there is almost no end to the number of handkerchiefs, linings, embroidery threads, warps, and so forth that are treated by the caustic soda process. The goods are immersed in a strong lye at a low temperature, with the effect that they contract, if allowed, become gelatinous and translucent in appearance, and gain a marked affinity for dyestuff. Other reagents than caustic soda have been proposed at various times, but it is probable that none other is used, and its cost is economised by recovery of soda from the spent liquor. The trouble of effectively neutralising and washing out the alkali, which in earlier days led to the rotting of goods treated by the process, is no longer felt, and the method has long been perfectly systematised and understood. Professor Knecht has shown recently that strong acid may be substituted for strong alkali, and it will be interesting to see how his process progresses in practice. Hydrochloric acid of 37-38° Twaddel is used in the bath, and is effective in thirty seconds. It is found that the acid does not enfeeble the fibre, is easily washed out, and is cheap, albeit the acid is not a commercial article in this strength.

British Dyestuffs.—British dye manufacturers hold out some hope of overtaking the demand for their present products in a month or so. Their facilities have been very heavily overtaxed in keeping the dyeing trade going, and their plants are being largely increased. Messrs. Read, Holliday & Sons, Ltd., of Huddersfield, whose works are to form a nucleus for the national colour-manufacturing scheme, are extending their premises over 15½ acres. Some smaller concerns are growing also, and there are prospects of the foundation of a new enterprise by firms who have hitherto acted as German agents in this country. The position of dyers in respect of stock on hand and contracts of delivery doubtless differs from case to case, but some of them are able to see their way forward for as far as one year. Aniline and naphthalene dyestuffs continue to filter in from Switzerland, where there are important works, and the supplies from foreign sources in the four months August-November have been some 19,000 cwt. as compared with 92,400 cwt. in the equal period of 1913. Dyers have had to refuse to bind themselves to deliver goods dyed to any shades that a customer may at any time choose to send, but thus far everything needing dyeing has been dyed in one manner or another, and the dread prospect of having to wear white or natural colours is indefinitely postponed.

NOTES ON BOOKS.

Liquid Drops and Globules. By Charles R. Darling. London: E. & F. N. Spon, Ltd. 2s. 6d. net.

In this little volume Mr. Darling has collected three lectures delivered to popular audiences. They deal with the formation and movements of liquid drops and globules, and with the phenomena connected with the surface skin of water and other liquids. The subject is one that, in the hands of a clever manipulator, lends itself to some beautiful experiments. Particularly pretty are those of the diving drop of dimethyl-aniline, the automatic drops of aniline, and the orthotoluidine globules on a water surface. Mr. Darling gives a very clear account of these, and a short appendix contains a list of the necessary materials, which are of a surprisingly simple nature. Any boy with a taste for science into whose hands this book may fall will almost inevitably be impelled to try the experiments described. He may not find them quite so easy to carry out as they appear to be when Mr. Darling is the manipulator, but if his interest is aroused, and he is led to a further study of the subject, the book will not have been written in vain.

Magnetism and Electricity. By S. S. Richardson, B.Sc., A.R.C.Sc. New and Revised Edition. London: Blackie & Son, Ltd. 4s. 6d.

In preparing the second edition of this work Mr. Richardson has revised the whole of the text, and re-written a considerable portion of it, with the result that it is now a very clear hand-book for the student who is preparing for the Board of Education Examinations, or for the Intermediate and the greater part of the Final Pass Degree Examinations of the Universities. A fresh chapter has also been added dealing with the principles underlying the actions of dynamos and motors. The author, as the head of the Physics Department of the Central Municipal Technical School of Liverpool, has a very accurate knowledge of the needs of students, who will find in this volume a lucid and efficient guide to the study of electricity and electrical measurements.

GENERAL NOTES.

Sugar-beet Culture.—An attempt is being made by the London and South-Western Railway Company to encourage sugar-beet culture in the south-western counties. The *Times* states that the company has had an extensive survey made of the soils in the counties of Surrey, Hants, Wilts, Dorset, Somerset, Devon, and Cornwall, and it is declared that large areas in these counties are thoroughly suitable for the cultivation of beet. The next step was to get the necessary co-operation between the farmer, the carrier, and the manufacturer. A meeting of Wiltshire landowners and farmers has already been held at Salisbury. Many of the leading farmers of the district were present, and addresses were given by Mr. Cadogan Rothery and other experts. It was announced that, given the requisite production of beet, the capital for the foundation of a factory (some £130,000) would be forthcoming, and every accommodation in the way of sidings and carriage facilities would be provided. Similar meetings are to be held early in the new year at Basingstoke, Fareham, Winchester, and possibly at Yeovil and other centres; at each of which the case for beet culture will be placed before the landowners and farmers, while each meeting will be prepared for, as the Salisbury meeting was, by the issue to all concerned of the company's booklet on the subject. The difficulty hitherto experienced in attempts to introduce the industry to England has been in the provision of the large capital required for each factory, which cannot be raised without a guarantee of sufficient permanent production from the locality. The peculiar circumstances of the time have made it possible to arrange that all capital required can now be raised. The result of the Salisbury meeting was that the matter was referred to the South Wilts Chamber of Agriculture.

The Brent Valley Bird Sanctuary.—At a recent meeting of the Linnean Society Mr. Wilfred Mark Webb described the circumstances under which the Brent Valley Bird Sanctuary came into existence. He said that twelve years ago the Brent Valley Branch of the Selborne Society took steps to protect a wood of nineteen acres in its district, not far from Ealing, which had long been known as an abiding place for birds. The immediate object was to preserve the nightingales; and a small committee was formed to approach the tenant of the farm on which the wood was situated with a view to the appointment of a watcher. Ultimately, the committee appointed its own keeper, took over the wood from the farmer, and now rents it direct from the owners. No very rare birds occur in the wood, but it is important in the neighbourhood of large towns to give an opportunity to the commoner kinds of nesting undisturbed. Forty-one species have been recorded as breeding in the wood, thirty-nine of them during recent years. Among these may be mentioned the nightingale, lesser white-throat, the blackcap, garden-warbler, chiffchaff, willow-warbler, long-tailed tit, marsh-tit, tree-creeper, hawfinch, goldfinch, redpoll, nuthatch, wryneck, cuckoo, red-backed shrike, turtle-dove, and wild duck. Including the winter migrants and occasional visitors, eighty-eight species have been observed in or close to the wood. Of these the golden-crested wren, all the three British woodpeckers, the nightjar, the brown owl, the barn owl, the snipe, and the kingfisher are seen commonly or from time to time. Owing to the introduction of nesting-boxes, several species have increased in numbers or have been induced to nest. Mr. Webb also pointed out that the work of the committee

had spread far beyond the confines of the wood, as many visitors and others had been provided with boxes by the committee, which was led some three or four years ago to make an effort to replace the boxes imported from Germany by English-made ones, which were considered to be of improved pattern. The expenses of the wood have been met by voluntary contributions and with the profits made by the sale of the nesting-boxes. It may be added that boxes have been sent to China, America, Italy, to the Pyrenees, and to France.

Nipa Palm Sugar.—An article in the *Philippine Journal of Science* gives some information concerning the nipa palm (*Nipa fructicans*) as a commercial source of sugar. The palm covers some 45,000 acres in the Bulacan and Pampanga provinces of the Philippines alone. Hitherto the sap exuded by the flower-stalk has only been utilised on a large scale as a commercial source of alcohol; it was examined by the writers of the article with regard to the possibility of extracting the sugar contained. The yield amounts to about 9½ gallons per tree per season, or, with 750 trees per hectare, to 2,650 gallons per acre. As it flows from the palm the sap contains about 15 per cent. of saccharose, and has an apparent purity of not less than 85, only traces of invert sugar being present. The addition of about ·5 per cent. of sodium chloride slightly reduces the purity; but waxes, acids, pectins and other foreign materials are practically absent. The sap contains active enzymes of the invertase and peroxidase types, the latter being present only during the final period of secretion and being capable of oxidising sucrose and invert sugar in neutral or alkaline solution.

Embargo on Exports of Dyestuffs from Italy.—It appears, from a memorandum issued by the *Museo di Commercio* of Milan, that the embargo on the exports of certain dyestuffs from Italy has been partially removed. The export of tannic acid is now permitted, but is restricted in quantity to that exported in 1913, which amounted to 258,479 quintals (25,145 English tons), or on the average of 21,290 quintals (2,095 tons) per month. The re-exportation of valonia, which comes from the Levant and principally Turkey, however, is still strictly prohibited.

The Port of Zeebrugge.—The following particulars respecting the little port of Zeebrugge, given by the Parisian journal *Le Temps*, will be of interest at the present time. As a base for submarines, this place was seized by the Germans as a favourable station for their raids in the Channel. Their plans have, fortunately, been frustrated by the recent bombardment by British ships. The outer harbour at Zeebrugge, at the entrance to the ship canal to Bruges, was opened in 1907. It is formed by a curved breakwater 2,487 metres (2,700 yards) in length, extending into the sea, and enclosing an area of 138 hectares (340 acres) of water, with a depth varying from 8 to 9½ metres (26 ft. 3 ins. to 31 ft.) alongside the quays, and affords a safe shelter for ships of large tonnage. The ship canal to Bruges, a distance of about 15 miles, is 70 metres (230 ft.) wide at the water level, and a depth of 8 metres (26 ft. 3 ins.). The cost of the work, which occupied thirteen years in construction, amounted to 50 millions of francs (2 millions sterling).

Cost of Reinforced-concrete Bridges.—In the course of a paper read before the Institution of Civil Engineers, Mr. J. B. Bull gave some information regarding the cost of reinforced-concrete bridges erected during the last six years by the Great Central Railway Company, A three-span bridge at Ashton-under-Lyne, reinforced with round bars on the Hennebique system, cost £5,917. The estimated cost of a similar structure in steel and masonry was £8,390. A bridge carrying a new road and tramway over the Grimsby district light railway, also designed on the Hennebique system, cost £2,939. The estimated cost of a similar structure in steelwork and masonry was £3,500. Four high-level railway bridges at Immingham Docks cost, on an average, £3,024 each. Similar structures in steelwork and masonry were estimated to cost £3,800 each.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 20.—J. A. Hunter, "The Textile Industries of Great Britain and of Germany." Lord Rotherham, President of the Textile Institute, will preside.

January 27.—Hon. John Collier, R.O.I., "Portrait Painting." Lord Sanderson, G.C.B., K.C.M.G., will preside.

February 3. — Octavius Charles Beale, Chairman of the Australian Manufacturers' Association, "Imperial Industrial Development after the War."

February 10.—F. Vincent Brooks, "British Lithography in 1915."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 21.—Henry John Elwes, F.R.S., "Nepal." The Right Hon. Sir Herbert Maxwell, Bt., F.R.S., will preside.

February 11. — Captain Sir George Duff Dunbar, Bt., I.A., "Tribes of the Brahmaputra Valley."

March 18. — Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army."

April 15.—M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 26.—MAJOR E. H. M. LEGGETT, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda."

FEBRUARY 2.—EDWARD R. DAVSON, "Sugar and the War."

Dates to be hereafter announced:—

THOMAS WORTHINGTON, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. THORNE BAKER, "The Industrial Uses of Radium."

FRANK BAINES, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. HULME, "Patent Law."

H. M. THORNTON, "The Industrial Uses of Coal Gas."

D. Y. CAMERON, A.R.A., R.E., "Etching."

ROGER FRY, "Post Impressionism in Design."

C. H. SHERRILL, "Ancient Stained Glass."

A. S. E. ACKERMANN, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

LADY LUGARD, "The Work of the War Refugees' Committee."

WILLIAM POEL, "Shakespeare's Profession."

ARTHUR WILCOCK, "Designing for Textiles."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—
April 15, May 13.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—
March 2, 30, May 4.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DR. F. MOLLWO PERKIN, F.I.C., F.C.S., "Oils, their Production and Manufacture." Three Lectures.
January 18, 25, February 1.

M. H. BAILLIE SCOTT, "House Building—Past and Present." Three Lectures.
March 15, 22, 29.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.
April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evenings, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." Three Lectures.
February 15, 22, March 1.

JUVENILE LECTURES.

Wednesday afternoons, at 5 o'clock:—

H. PLUNKET GREENE, "How to Sing a Song." Two lectures, with vocal illustrations.
January 6, 13.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 4...Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Professor D. S. Margoliouth, "The Life Work of Homer."

Geographical Society, Town Hall, High-street, Kensington, W., 3.30 p.m. (Juvenile Lecture.) Mr. C. Carus-Wilson, "The Earth's Unstable Crust."

Chemical Industry, Society of (London Section), Northampton Polytechnic Institute, Clerkenwell, E.C., 8 p.m. Mr. E. Kilburn Scott, "Production of Nitrates from Air, with special reference to a New Electric Furnace."

TUESDAY, JANUARY 5...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor C. V. Boys, "Science in the Home. Lecture IV.—Heat in the Home."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 3.30 p.m. (Juvenile Lecture.) Mr. R. Kearton, "Wild Beasts and Birds of the British Empire."

Röntgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. Discussion on the "Localisation of Foreign Bodies by X-Rays."

WEDNESDAY, JANUARY 6..ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lecture.) Mr. H. Plunket Greene, "How to Sing a Song." (Lecture I.)

Geological Society, Burlington House, W., 8 p.m. 1. Mr. C. I. Gardiner, "The Silurian Inlier of Usk." 2. Mr. J. R. Haselhurst, "Some Observations on Cone-in-Cone Structure, and their Relation to its Origin."

Civil Engineers of Ireland, Institution of, 35, Dawson-street, Dublin, 8 p.m.

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 8 p.m. Presidential Address by Mr. A. P. I. Cotterell.

THURSDAY, JANUARY 7... Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 3.30 p.m. (Juvenile Lecture.) Mr. W. H. Garrison, "The World's Greatest War."

Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor C. V. Boys, "Science in the Home. Lecture V.—Electricity in the Home."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. H. J. Tingle, "The Application of Concrete in Modern Sanitation."

FRIDAY, JANUARY 8...Geographical Society, Town Hall, High-street, Kensington, W., 3.30 p.m. (Juvenile Lecture.) Rev. T. T. Norgate, "The Theatres of War Illustrated."

Geologists' Association, University College, W.C., 8 p.m. Miss G. L. Elles, "The Value of Graptolites to the Stratigraphical Geologist."

Journal of the Royal Society of Arts.

No. 3,242. VOL. LXIII.

FRIDAY, JANUARY 8, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 13th, 5 p.m. (Juvenile Lecture.) H. PLUNKET GREENE, "How to Sing a Song."

The lecture will be accompanied with numerous vocal illustrations.

Further particulars of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

On Wednesday afternoon, January 6th, Mr. H. PLUNKET GREENE delivered the first lecture of his course on "How to Sing a Song."

The lecturer began by considering what special gifts a public singer must possess in order to attain success on the platform, and how these gifts must be trained. As an instance of the singing possibilities that lurk in the majority of people, he mentioned the case of a Liverpool man who undertook to train some children to sing. At the beginning of their course they had not even the most rudimentary notions of music. He began by teaching them the meaning of the words of their songs and the beauty of the ideas which they expressed; he then gradually led them on to see how this beauty could be magnified by the music, and by the end of a year they were able to sing with feeling and expression.

In singing, said Mr. Plunket Greene, there were two problems: first, how to sing at all, *i.e.*, how to make the sounds; and, second, how to use those sounds when one had learnt to make them. That afternoon he proposed to deal mainly with the first problem; in next week's lecture he would discuss the second. There were four things, apart from the voice, which a singer must possess. (1) He must be master of his technique; he must know how to breathe properly, and how to pitch his voice in the right place—the tip of the tongue; he must be able to sing fast or slowly with equal ease, and he must always take care to make the words absolutely clear. (2) Every song has its own atmosphere, and this he must be able to realise and express. He must think of the song as a whole, and to do this effectively he must possess imagination. (3) He must be able to express tone colour; and (4) he must possess magnetism. This was essentially an individual gift; it was a difficult thing to define, but it meant in effect that the fortunate singer who had it and his audience were at once on friendly terms.

Having discussed and illustrated the qualities of a successful singer, Mr. Plunket Greene next proceeded to lay down the three principal rules which he must faithfully observe. In the first place, he must never stop the march of the song—that is to say, he must never break the rhythm in order to take breath. He must learn to manage his breath so that he can take it when the rhythm permits. Secondly, he must rememember that he is not the only person to be considered when singing a song. The song begins as soon as the first note is played on the piano, and it does not end until the last note has sounded. The accompaniment is just as important as the words, and the accompanist as the singer. Lastly, a singer should remember that the speech he sings is the same as that which he talks: there should be no fanciful pronunciation of words for the supposed reason that some sounds which can be spoken quite well cannot be easily sung. He quoted a number of instances in which the drawing-room singer is apt to travesty the English language, and finally, in illustration of his various points, he sang the following songs:—

1	The Hurdy-Gurdy Man	Schubert
2	Cradle-Song of the Shepherds at Bethlehem	Chr. Dan. Schubart (1791)
3	Did you ever?	C. V. Stanford
4	The Sands o' Dee	Frederick Clay
5	The Song of Momus to Mars	Dr. Boyce (1750)
6	Speed on, Engine	Francis Korbay
7	The Crow	C. V. Stanford
8	The Kilkenny Cats (Old Irish)	*Arranged by* C. V. Stanford

A distinctive feature of the illustrations were the highly skilled and sympathetic accompaniments of Mr. S. Liddle.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE HISTORY AND PRACTICE OF THE ART OF PRINTING.

By R. A. Peddie,
Librarian, St. Bride Foundation Typographical Library.

Lecture III.—Delivered December 7th, 1914.

The Nineteenth Century (Part II.) and After.

The development of printing during the second half of the nineteenth century was rapid in the extreme, at least on the mechanical side. Machine succeeded machine, each more rapid and effective than the last. Processes of illustration were born and died, giving place to more rapid and accurate methods. Up to about the year 1890 it cannot be said that a similar advance took place as regards type and type design. If this period showed no development in the printed book, it at least was a period in which the book was produced in a solid manner. In the decent class of book the type was Revived Old Style or Caslon Old Face, the paper was a sound printing paper without any mixture of wood-pulp, china clay, or any of the other abominations of a later period, and the binding cloth was good and strong. The one-volume novel of the sixties or seventies will be found to-day in good order, showing signs of age perhaps, but wearing out, not falling to pieces, as our modern books do after about three people have handled them.

In the late eighties there was a curious epidemic among printers of the use of colour in letterpress work. This was, of course, mostly in job work, but it spread to book work, and there are monstrosities to be found in the way of decorated titlepages in many colours which are calculated to make anyone interested in good printing feel very ill. This curious movement was known, for some obscure reason, as Art Printing. These printers liked to use tint blocks and scroll work and ornamented initials and borders, and all without any idea of the real value or balance of the printed page. The "artist printer" of this period was the man who got most eccentric designs and colours on to the sheet of paper. Luckily for us all, a change was caused by the foundation of the Kelmscott Press by Mr. William Morris. The influence of this Press cannot be overestimated. Morris restored handmade paper, black ink, and good press work to a position that they had lost for many years. The archaic character of his types, which one must admit was carried almost to excess, was one of the most important factors in this revolution. The buyers of modern books, many of whom perhaps had never seen a fifteenth century book, were simply taken off their feet by the magnificence of the Kelmscott Press books. We, of course, know them so well that we take them for granted; but imagine the collector of the editions de luxe of the 1890 period, with their thin type and almost finicking get-up, seeing the "Golden Legend" for the first time. Morris set a fashion of good printing, and even of plain printing, because although the Kelmscott Press books are decorated, they are decorated, as it were, in addition to the printed page. I do not think there is much doubt that Morris would have preferred to illuminate every copy himself, but this being impossible he allowed his designs to be printed at the same time as the letterpress. Morris's designs were personal to himself, and it is perhaps as well that all the ornaments of the Kelmscott Press were withdrawn from use on his death. The type can be used according to his rules, and has been so used with effective results. The types of the Kelmscott Press were three in number. The Golden type, a Roman based on Jensen's letter but with a slight admixture of Gothic style; the Troy type, a round Gothic; and the Chaucer, a smaller Gothic. The Golden type has been copied and modified by many typefounders, and, of course, often spoiled in appearance. The Gothics have not had so much attention paid to them.

The Doves Press was founded by Mr. Emery Walker and Mr. Cobden Sanderson. The type cut for them was a very plain and handsome Roman with a thinner face than that of the Kelmscott Golden type. The style of the Doves Press is one of great restraint. Ornament is unknown, and only here and there is found an initial in red of a striking and effective character.

The type used by Mr. St. John Hornby at his Ashendene Press is based on the Subiaco type of Sweynheym and Pannartz, and is therefore to be described as a semi-Roman. It is effective, and the great Dante of the Ashendene Press is worthy to rank with the Kelmscott Chaucer and the Doves Bible. These three books may be described as the ideal books of modern typography.

The type specially designed by Mr. C. R. Ashbee, for use at the Essex House Press, in printing the King Edward VII. Prayer Book, will be noticed as distinctly different from the

other types mentioned, and it certainly is not so successful. The letters contain too much added ornament. Sufficient reliance is not placed upon plain lettering.

These Presses, to which must be added the Vale Press with a very excellent Roman fount designed by Mr. Ricketts, had a great effect on printing. They created a demand for sound Roman type, and although the printer was only slowly educated up to supplying the demand, and occasionally would make such "bloomers" as to print Caslon Old Face on an art paper, still progress was visible. At times, in fact, the artistic movement went too far. A few years ago there was a passion for posters printed entirely in capitals. This had probably been induced by a study of inscriptions and of the Aldine Poliphilus of 1499. The result was our leading educational authority issued a series of posters containing perhaps forty or fifty lines of solid caps. They looked very nice, but were almost unreadable. Nothing is more dangerous than carrying a cult too far and forcing a process or method to do what it is not adapted for. A face of type may be good for an inscription of four or five lines and impossible in a page of fifty or sixty. All this simply means that theory and practice must work together, and only when they are in strict harmony will the result be really effective.

Typefounders' specimen books of to-day show a great advance from those of the early nineties of the last century. Even in America, where the jobbing types are often of the most eccentric character, the book types were quick to catch the note of the English revival. Morris's types were copied immediately, and in one form or another the new (and old) Romans are to be found throughout the better-class printing of the United States. Germany, of course, followed quickly. Not content with their modified Frakturschrift and the large number of Romans already at their disposal, every typefounder in Germany set out to design and cut new forms of letter. It is practically impossible for type designers to make a decent living in this country, but in Germany it is almost a profession. Goebel's great volumes issued every three or four years show the progress of the art in every department in Germany, and in no section is progress so marked as in that of type design.

Then, again, another great effect of the revival was to draw attention to the correct placing of the type on the page, and to the fact that the opening of two pages of a book is the unit and not the single page. These matters are much better looked after now than they were, and English books have a much better appearance in consequence.

To-day, except for a slight want of originality in type faces, British book printing can bear comparison with that of any country. For book work this country has been almost without a rival for two hundred years. Apart entirely from the private presses I have mentioned, great commercial houses, such as the Chiswick Press, have carried on the tradition of good, solid and artistic work.

There is unfortunately another and a larger section of the printing trade which cannot be said to hold its own in comparison with the work of other countries, and that is ordinary job printing. Prospectuses, advertisements, and other work requiring artistic design and a knowledge of the circumstances of the publication and the resources of the printing office, do not compare favourably with similar work issued in many other countries. A correspondent in Vienna used to send me every year a parcel of ordinary job printing of this kind—good, bad, and indifferent. On looking over the items it was seen that the good prevailed. Similar collections made here do not show the same result. This may be due to the different conditions attaching to technical education. Here, more attention is paid to rapid production and to the teaching of the mechanical art. If artistic training in typographical design is to be had, it is very often divorced from the rest of the course. I would suggest that this is not so in other countries, and that the tremendously rapid advance in artistic typography seen in Germany during the last twenty or thirty years is due to the fact that they have found some method of bringing together theory and practice—of harmonising artistic design with the mechanical trade.

The greatest change in printing is the introduction of typesetting machines. This was one of the great ideals of inventors, and from about 1840 a continuous succession of inventions made their appearance. Generally their exit followed very quickly. The *Family Herald*, a well-known journal to-day, made its first appearance in 1842 in ordinary newspaper folio form with the picture of the composing machine by which it was set up in the head-line. The *Times* was set up by the Kastenbein machine for many years, latterly with new type daily made by the Wicks Rotary Type Caster. The Thorne machine was a considerable success in the

eighties. These machines all took type as it came from the founder. The type was arranged in funnels and fell into place when a key was struck. They generally had a subordinate machine called a distributor to arrange the type in proper order. The invention of the Linotype in 1884–85 brought a new principle into play. Instead of using type, the pressure of a key brings down a matrice of that letter. A line of these matrices automatically justified is carried to the front of the metal pot, where a line of type is cast in solid form from it. During this time the operator is assembling the next line of matrices. When the operation of casting is complete, the slug is automatically shot into a tray and the matrices are taken up by an arm to the back of the machine and hung on a bar. As they are pushed along this bar they fall automatically into their right boxes, and are ready to be used again when required. The solid lines of type or slugs are arranged in a galley, and after correction are ready to be printed from. Most newspapers are set up in this way to-day. After stereos have been made from them the slugs can go back to the metal pot and be used over again.

The Lanston Monotype is on a different principle. It is a type-casting machine casting separate types and actuated by a perforated roll of paper on the Jacquard principle. The keyboard is used for perforating the paper, and the operator at the keyboard has nothing to do with the caster, which may be in another room or another country. In fact, the perforated paper can be sent to America instead of sending stereos, and can be put on a caster there, and the type will be produced in exactly the same manner as if it had gone straight to the caster here. Both machines are actuated by compressed air, and the action of the paper on the caster can be compared to the same kind of perforated paper used on a pianola. The matrix used is a plate of steel about 4 ins. square. On this is found the full alphabet, together with the various sorts necessary. It is actuated by a very wonderful series of levers, which enable it to take position so that any letter or figure may be cast. The work is very rapid, and corrections can be made by substituting single types, whereas in the Linotype the complete line has to be recast. The *Times* is set by Monotype machines, and a great deal of book work is done on them. A new attachment to the keyboard enables the operator to set two editions of a book at the same time, say a 6*s.* novel and the same book in 7*d.* form. The 6*s.* edition can then be set up by the caster and when the time comes for the 7*d.* edition the other roll of paper can be at once put in hand without any further work on the keyboard.

These two machines have revolutionised printing. All our newspapers and cheap books are produced in this manner. For display work and important books, however, hand-setting still holds its own, and although it is dangerous to prophesy, especially in an industry like printing with its rapidity of change, I cannot help thinking (and hoping) that it will continue to be supreme.

Photographic Illustration.

I now turn to the second division of my subject, the development of the processes of illustration

Although what we know to-day as photography, namely, the production of pictures by the agency of light, was brought to a successful issue by 1839, the action of light on a sensitised surface was known long before. Experiments had been made by Wedgwood in England, but he failed to fix the images he produced. Niépce in France was the first to produce a permanent photographic image. He coated metal plates with a varnish of bitumen dissolved in oil of lavender, and when dry he exposed them to the camera, afterwards developing the image by the solvent in which the bitumen had been dissolved, so that he obtained plates with the design in bare metal on a varnish ground. He also exposed his plates under line engravings, and these plates he etched, so that he was able to print from them in a copperplate press. The earliest known example of his work is a portrait of the Cardinal d'Amboise, said to have been printed in 1824. Niépce's process was perfected by his nephew Niépce de St. Victor. The bitumen process first used by Niépce was afterwards developed and extensively used for the production of printing surfaces in intaglio and relief. The next important discovery was that the combination of gelatine and bichromate of potash after exposure to light became more or less insoluble, and therefore impermeable to an etching solution such as perchloride of iron. So by coating a plate of steel or copper with a film of these materials and exposing it to light through a photographic negative, it became possible to etch the plate in proportion to its exposure. This is Fox Talbot's method of photographic engraving of 1852 and 1858, and also forms the basis of modern photogravure introduced by Karl Klic in 1879. This type of

film is also unabsorbent of water in proportion to the action of light, and if placed in cold water after exposure will swell up unevenly and form a relief or mould from which casts can be made in plaster or by electrotyping. This forms the basis of Pretsch's process in 1854, and generally of photo-galvanography or photo-electrotypy. Again, the same type of film exposed to light under a negative, then moistened with water like a lithographic stone, and inked with a roller and printing ink, will only take up the ink in the exposed parts in proportion as the action of light has rendered the film unabsorbent of water. This is Poitevin's process of direct photo-lithography (1855). If the exposed film be inked up without wetting and then placed in warm water, all the unexposed gelatine will dissolve, leaving ink only on the image, which may be transferred to stone or printed from direct, in which latter case it corresponds with Tessié de Mothay's photocollotype (1865).

Parallel with these efforts for the reproduction of tones, there were similar efforts for the reproduction of line work, and, following the discovery of photo-lithography, these were at last successful.

It was discovered by Gillot in 1872 that Fox Talbot's old method of making intaglio plates could be utilised for making relief blocks. The following description will be seen to be almost the same as the earlier method.

A zinc or copper plate sensitised with albumen and potassium bichromate is placed in a printing frame with the negative, and the picture obtained by exposure to light. The plate is then inked and washed, the surplus ink comes away, and the picture remains visible. Asphaltum is then dusted on to the plate, which is then etched to a sufficient depth to give a printing surface. This is one of many methods which differ only in the chemicals used and the elaborations introduced for special work.

Many processes were in use by the seventies and early eighties, but none of them really reproduced all the tones of a picture from the high lights to the deep shadows, and at the same time produced a block which could be printed with letterpress and by the ordinary machine. What was wanted was some method of breaking up the tones of a photograph into lines and dots so that a relief block could be made from it. The early experimenters used screens of crape and similar fabrics, but without much success. Somewhere in the early eighties glass-ruled screens were introduced, which were turned round during the exposure; and finally Mr. F. E. Ives, in the winter of 1885-86, sealed two single-line screens together and made the cross-line screen which is used to-day. This screen varies from 50 lines to 400 lines to the inch. This made the half-tone process possible. The only difference between the actual preparation of the half-tone plate and the line plate previously described is that the negative for the half-tone is taken through the cross-line screen, thereby breaking up the picture into a series of dots.

The latest development of photo-engraving has been in the direction of mechanically printed photogravure. This process, based on Talbot's and Klic's discoveries, is an intaglio method and not relief. A print is made through a screen of transparent thin lines and crossing each other on photogravure carbon tissue. This tissue is laid down on a copper plate for flat printing, or a copper cylinder for rotary work. It is then developed and etched. The lines of the screen being so fine are just sufficient to hold the ink on the cylinder; but when printed the ink runs slightly, with the result that in the deep tones the screen lines are invisible. By the most recent developments it is possible to print, not only the pictures in a magazine or newspaper, but the letterpress as well. This is set up and photographed at the same time as the pictures. It is generally possible in the inscriptions under the prints to see the lines of the screen.

Other Methods of Illustration.

Revival of wood-engraving took place in the sixties; but although great artists drew for the wood and on the wood, the wood-engraver himself did not rise to the occasion, and it was a period of great illustration not always successfully carried out. I will quote what Mr. Gleeson White says in his important work on this period:—

"Soon after this revival wood-engraving as a trade began to feel the photographic competition. By the time the half-tone process was established it was dying, and it was very soon quite dead."

Lithography, on the other hand, has acquired additional strength during the photographic period. The most adaptable of reproductive methods itself, it has adapted photography. As printing machinery developed so lithography developed, and from the hand-press method of the early nineteenth century we see it using the power press in the early fifties, adopting the new metal aluminium as soon as

it was cheap enough, and then using great sheets of it in a rotary machine for printing posters and other large work. Finally, an accident led to the invention of the offset method of printing, which enables lithographs to be printed on any surface of paper. The offset press has a rubber cylinder introduced between the stone or aluminium sheet and the impression cylinder; so that, instead of the hard surface of the stone or plate coming in contact with the paper, the yielding surface of the rubber takes up the design and transfers it to the paper. A much softer impression is obtained with good results. Like all new processes, it was set at once to do work which it was not adapted for, with disastrous results; but as printers have got to know the limits as well as the possibilities of the method, they have succeeded in obtaining better and better results.

Printing Machines.

The third section of this lecture deals with the development in printing machinery from about the middle of the nineteenth century. We have still to deal with the three classes of machines—the platen, the flat-bed cylinder, and the rotary. Although it is not strictly correct chronologically, I propose to take them in that order. The hand press it is unnecessary to deal with, as its history was finished in my last lecture. But the platen machine is a development from the hand press. The platen and the bed are still there, but no longer horizontal, but vertical. The original inventor of this machine was an American, Geo. P. Gordon. The bed is fixed and the platen is forced up to it by steel arms on either side. The platen then returns to its open position, and remains so long enough for the operator to take the printed sheet out with his left hand and lay on another with his right. This press in its various forms is pre-eminently the small jobbing press, although the heavier presses are used considerably for colour work.

The flat-bed cylinder machine began its period of great success soon after 1850. The Main machine, previously referred to, is dated about 1850, and from that time progress has been continuous. Koenig's continuously revolving cylinder of his 1811 machine is now found in the drum-cylinder machines, principally used in America.

The single-revolution or Wharfedale machine, in which the cylinder stops after each revolution to allow of the backward traverse of the bed, came into use about 1860, and has been much improved since then. In the two-revolution machine, of which the Miehle is a type, the cylinder makes two revolutions to each to-and-fro motion of the bed, but during the reverse movement of the bed the cylinder is lifted clear of the type. The two-colour machine enables two colours to be printed on the one sheet before it leaves the press. There are two formes, one at each end of the bed.

The final section of flat-bed cylinder machines is that of Perfecters. These machines print single sheets on both sides during their traverse from the feed-board to the delivery-board. They have two large cylinders instead of one. This type of machine is gradually dying out, being attacked by the fast Wharfedale machine on the one hand and by the rotaries on the other. Of late years the addition of automatic paper-feeders, mostly pneumatic in action, has quickened up the action of printing machines using flat sheets.

Turning to Rotary machines, I carried their history up to the introduction of the Walter machine into the *Times* office in 1868. This was the first machine to print on the roll of paper, from curved stereos, to perfect the sheet and produce a complete newspaper. These machines were used by the *Times* until 1895. Folding mechanism had been attached to them about 1885.

The development of the newspaper machine during the twenty years following the introduction of the Walter Press was slow. Single-roll machines were the rule rather than the exception, and the increasing circulation was met by putting in fresh machines. The newspapers during the period 1870–90 were only four to eight pages, and this was the limit of the machines then used. The competition, however, added to the cheapness of paper, resulted in an enlargement to twelve pages. Such enlarged issues could not be printed on one machine. The extra pages had to be added by hand. This resulted in the construction of machines that would produce newspapers of a varying number of pages, from four to twelve or sixteen, all inset, cut at the head, and folded in a more convenient form. It was found to be impracticable to produce these different sizes from a single web of paper; therefore several printing presses* were

* In England the distinction between the words press and machine is definite. Press is only applied to the hand press and the platen. All others are machines. In America the word press is applied to all. I have been somewhat indiscriminate in my use of the words, inclining more perhaps to the American than to the English use.

combined in one machine, each printing from a separate roll or web of paper and all conveying the printed sheets to the same folder, where they were incorporated in the one newspaper. Such is the multiple web machine of to-day. A classification of these combined machines may be made as follows :—

1. Two presses at right angles to one another and forming one machine. These are known as supplement or quadruple presses.

2. Two or more presses working one above the other with connection between each. These are known as two-decker and three-decker machines.

3. Two or more presses one behind another and capable of being coupled together to form a combined machine. This is called the tandem system.

4. Two presses arranged with a space between them where the folding mechanism is placed.

It may be said that there is no standard pattern of newspaper printing machines. The conditions in each office vary so greatly as regards space, both in area and shape, that each case is treated on its merits and special designs are made.

We now resume the history of the newspaper printing machine where we left it at the introduction of the Walter Press into the *Times* office in 1868. The Marinoni machine was introduced in Paris in 1868 for the purpose of coping with the increasing circulation of *Le Petit Journal.* This was not a web printing machine, but was the last and most rapid of the sheet-fed newspaper machines. Two of the machines were bought for the *Echo,* and that paper was printed by them early in 1872. About 1874 Mr. Edward Lloyd introduced the first open-delivery Hoe machine, which printed from the web. Hoe rotaries had been used for some time previous to this date in America. The Hoe Double Supplement Press was introduced about 1887, and eight machines were installed to print *Lloyd's Weekly Newspaper.* This machine turned out four, six, eight, ten, and twelve-page papers at 24,000 per hour, and sixteen-page papers at 12,000 per hour, the odd pages being in every case accurately inserted and pasted in, and the papers cut at the top and delivered folded. This machine is of the right-angled variety mentioned above, and prints from two rolls, the one on the long side being twice the width of the other, which is only one page wide. In 1895 these were superseded by Hoe's three-roll presses, using single-width webs. These machines had three reels of paper at one end, and the supplement press at right angles was rendered unnecessary.

In the same year, 1895, the *Times* replaced the Walter presses by Hoe's three-roll machines.

Lloyd's three-roll single machines were replaced in 1901 by the three double-width roll or sextuple type. These produced double the output of the single machines and necessitated the use of two folders instead of one. In 1902 the order was given by Messrs. Lloyd to Messrs. Hoe for the first of the present battery of seven double octuple machines. These machines, which now print *Lloyd's Weekly Newspaper,* are the most powerful newspaper printing machines at work in this country at the present moment. They take four double-width reels of paper at each end, are four decks high, and are constructed in such a manner that another deck still can, if necessary, be added at the top. The capacity of each of these machines is 144,000 per hour, up to sixteen pages ; from eighteen to thirty-two pages, 72,000 per hour, and so on in proportion. The papers are delivered folded and automatically counted.

The latest improvement in newspaper printing machinery is the making of the stereotype plates by machinery. After the flong—that is, the paper matrix—has been made by pressing it on to the type, it is placed in the casting-box of the autoplate, and as many plates as are necessary are cast from it. They are trimmed automatically and are ready to go on to the press.

Rotary machines are also used for the big runs of popular journals, and if the journal has a coloured cover this is printed on a smaller rotary at right angles. The body of the paper and the cover are brought together at the folding mechanism, and the complete paper stitched in its cover is counted out in quires.

So we have seen in the last hundred years the development of the art we saw emerge from obscurity some 450 years ago. All the speed and wonderful power of production we have seen it gather is unfortunately not all gain. Worse printing can be and is done to-day than ever has been done ; but at the same time there appears to be some light in the darkness, some indication that the printer is taking more interest in his craft and is beginning to realise more of its possibilities. The good effects of the work of William Morris and Emery Walker are distinctly visible, and there is hope for the artistic future of the "Art preservative of all Arts."

THE PRODUCTION OF FINE SEA ISLAND COTTON IN THE WEST INDIES, WITH PARTICULAR REFERENCE TO THE ST. VINCENT INDUSTRY.*

At least 130 years ago a fine cotton, presumably Sea Island, was grown in the West Indies. Seed was sent to the United States, where, it is stated, a stock was gradually matured with an annual habit directly adapted to the climatic conditions of a limited tract of country. This special stock, according to Sir George Watt, embraces all the finest grades and most valuable cottons of the world, and is in fact true Sea Island, now known botanically as *Gossypium barbadense* var. *maritima*, Watt.

The cultivation of long-stapled cotton was never completely abandoned in the British West Indies, but was confined after the American Civil War to a small production in the Grenadines. The revival of fine Sea Island cotton-growing, however, dates from the year 1901, when small experimental plantings were made in this and the following year from seed obtained from the United States. The results were so promising that Sir Daniel Morris, then Imperial Commissioner of Agriculture for the West Indies, and Mr. J. R. Bovell, Superintendent of Agriculture, Barbados, paid a special visit to the Sea Island cotton districts of South Carolina and Georgia in 1903. The valuable first-hand information which these gentlemen obtained was of much value to West Indian planters. Besides, during his visit Sir Daniel Morris obtained a large supply of seed of the fine River's type, produced on the seaboard of South Carolina. This variety is still largely grown, as are also other fine varieties obtained through the British Cotton Growing Association and others. In the year 1905 the American growers of the finest Sea Island cotton combined to prohibit the exportation of seed; but this action had little or no effect on the West Indian industry, for it was proved by this time that with careful local selection and cultivation the quality of the cotton could be maintained and in many instances improved, with the result that to-day the finest cotton in the world is produced in certain of the islands.

The chief British islands exporting Sea Island cotton are St. Vincent, St. Kitts, Barbados, and Montserrat, but the industry is successfully carried on in several of the others. St. Vincent, besides being the premier cotton-growing island, also produces the most valuable cotton. In St. Kitts, however, where the soil and climatic conditions are somewhat similar to those of St. Vincent, some exceptionally fine cotton is grown. In the paper now submitted it is proposed to refer more particularly to the St. Vincent industry, because—

(*a*) The British Cotton Growing Association advises West Indian planters to cultivate for fineness of lint in view of the competition of certain Egyptian and American cottons with some of the cotton produced in the West Indies, but not with that of St. Vincent;

(*b*) The methods adopted in the production of cotton in St. Vincent and the measures taken for the protection of the industry have been under closer governmental control than in any other island; and

(*c*) The highest degree of success has been obtained in the production of fine cotton.

The soil of St. Vincent is of volcanic origin throughout, and may be classed as a dark sandy loam. With the exception of St. Kitts, the soils of other islands are, as a rule, heavier in character. The rainfall of St. Vincent is ample and often excessive, and exceeds that of the other Colonies.

Mention has been made of the introduction of the River's and other fine types from South Carolina, and it is from these that the successful local industry has been built up. Great care had to be exercised at the outset to ensure that only seed from the best fields of plants true to type was planted. The seed now used for planting is all obtained from nurseries or selected crop lots, and is tested, selected, and sterilised before being sown. The seed selected must be heavy and sound with a tuft of green fuzz at one or both ends. Arrangements are made with planters by the Agricultural Department to grow special fields from seed from selected plants at the experiment station in order to keep up the standard of cotton grown by small growers. Most of the large estates now maintain their own nurseries. The methods adopted in plant selection are based on desirable field characters of the plant, yield of seed-cotton, length, fineness, strength, uniformity, and lustre of the lint. Plant selection for resistance to certain bacterial and fungus diseases is also largely carried out and with promising results.

The work of maintaining the quality and yield of cotton in St. Vincent has been greatly facilitated by the enacting of certain legislative measures. Under the ordinance for the prevention of the introduction of pests and diseases power is given the Agricultural Authority to destroy, fumigate, or sterilise all seed-cotton or cotton seed brought into the Colony, and the provisions of the ordinance are strictly enforced. Under the Agricultural Products Protection Ordinance all sales of seed-cotton of a less amount than 100 lbs. in weight have to be made to the Government Central Ginnery, but lots up to 4,000 may be sold. The object of the action thus taken was to prevent cotton stealing, but as the Government wisely purchases the cotton on a profit-sharing basis there are few sales to licensed dealers. At the present time there is only one licensed dealer in the Colony, and the licence is held by a responsible firm who do not sell seed for planting purposes to the peasantry. As a result the seed supply is under close control.

* Abstract of a paper read by W. N. Sands, F.L.S., Agricultural Superintendent, St. Vincent, at the Third International Congress of Tropical Agriculture, London, 1914.

A third ordinance which has an important bearing on the industry is that providing for the destruction of all cotton plants at the end of each season in order to prevent the carrying over from one season to another of certain posts and diseases. As the provisions of this measure cover all kinds of cotton, whether wild or cultivated, it has been possible to destroy all the perennial wild or semi-wild types and so reduce to a minimum the danger of cross fertilisation of the valuable Sea Island variety with undesirable kinds.

The methods of cultivation, yields per acre, details of picking, bulking, drying, ginning, and baling are fully described in the paper, together with the chief characteristics of the lint and the uses to which it is put.

The prices obtained for St. Vincent Sea Island white cotton during the past three seasons have ranged from 2*s.* to 2*s.* 9*d.* per lb. for the "superfine" and from 1*s.* 6*d.* to 1*s.* 11*d.* for the "ordinary."

The industry is a remunerative one in an average of years.

THE FUTURE OF INDIGO.*

By Professor Henry E. Armstrong.

Under the title "The Downfall of Natural Indigo," a long letter from my pen was printed in the London *Times* of April 15th, 1901, in which the story of synthetic indigo was told at length. This may also be read in my book on "The Teaching of Scientific Method," published by Messrs. Macmillan & Co. I have followed the development of the industry in the interval. Recently, during my short stay in India, I have endeavoured, especially when visiting the Agricultural Research Institute at Pusa, to learn as much as possible of the state of the Indian grower.

With reference to the article in *The Statesman* of November 14th, on the "Indigo Trade Revival," may I say at once that Mr. Bridgett displays the usual prejudice in asserting that natural indigo "makes the very best and fastest dyes, whereas the German chemical substitute gives a dull, dead colour which often washes out." It is nonsense to talk of the real indigo "having the natural energy put into the plant by the sun"—the natural and the artificial article are one and the same chemical substance. If the natural article be so superior, why has the industry languished? I should advise Government to do nothing until they have a guarantee that the planters will bestir themselves. Our foolish if not criminal policy of allowing the Indian industry to be supplanted is the result of indifference, if not of ignorance and of the inability of those concerned to take combined action in placing it on a scientific footing. I have recently had the opportunity of inspecting the Government quinine factory and cinchona plantations near Darjeeling, and have seen what scientific acumen has done to place this industry on a satisfactory footing. Not so long ago it was more or less a failure, I understand. There is little doubt that if real intelligence had been directed to the indigo problem, that also would have been solved, though I am free to confess that the task is a difficult one. Thirteen years ago, in the letter referred to, I wrote: "Of one thing we may be certain, that if indigo planters desire to retain any share of the industry, they must not only seek to improve the methods of cultivation and of extracting the dye-stuff, but they must be prepared to refine the natural product and supply a practically pure article. Even in indigo dyeing the days of the rank empiricist are numbered, and the certainty which attends the use of pure materials in fairly skilled hands will have its inevitable influence." This has proved to be the case. The preparation of the indigo-vat, in days gone by, was a difficult matter, in the hands of a few skilful people, but these were empiricists. Since synthetic indigo came into the market dyers have been supplied with a paste containing a fixed, known proportion of the dye-stuff, not an ever-varying proportion, as is the case when the natural product is used. Improved methods of preparing the dye-bath have been introduced, and the operations of the dyer greatly simplified. In the case both of artificial madder and of artificial indigo, however, the natural dye-stuffs have been ousted not merely through the production of the substitutes at cheaper rates, but more particularly through the introduction of articles of standard strength, and the consequent simplification of the dyer's work. If the advantage gained by natural indigo through the war is to be maintained, I believe it will be necessary for planters in future in some way to arrange to bulk their products and put upon the market a paste of fixed composition comparable with that supplied by the Germans.

I cannot help thinking that it should still be possible to secure a fair share of the trade for natural indigo in competition with the synthetic article. The possibilities in the way of effecting improvements, especially in agricultural practice, in the plant itself and in the process of manufacture seem to be in no wise exhausted. Our understanding of such matters is now so much greater than it was even ten years ago. Various inquirers have studied this or that side of the problem, but apparently no attempt has been made to deal with the subject comprehensively from the many points of view from which it must be regarded if success is to be assured. The men who have been engaged have not had the all-round knowledge or the ripened ability as investigators that is required to deal with the many issues, scientific and economic, that are involved. It cannot be insisted too strongly, in fact, that the problem is one requiring very special knowledge

* This article, reprinted from *The Statesman*, of Calcutta, of November 17th, 1914, was written by Professor Armstrong in reply to another on the "Indigo Trade Revival."

and acumen. But it is nothing short of a disgrace to us that such an industry should be allowed to lapse in a country where the need of native industries is so great. The recovery of the position of natural indigo may be a costly business, but if one-tenth of the zeal put by the Germans into the production of the artificial pigment be brought to bear on the problem, I believe it will be solved satisfactorily.

LABOUR CONDITIONS IN NAPLES IN 1913.

During 1913 Italy generally, and especially the consular district of Naples, was characterised by a tendency towards over-industrialisation, which, as in many other countries, has had regrettable results. The land has been neglected in favour of industry, and emigration has powerfully exercised its allurement of better wages for women as well as men. The flower of the population is continually flowing out of the country, and the land thus remains to be tended by an agricultural population of a lower standard. If greater attention were paid to the land and its capabilities under up-to-date culture the attractions of emigration might be greatly diminished. In some localities, too, re-afforestation would yield considerable advantages. But of course the prime necessity is money and, following on that, more elastic fiscal regulations. Just at present the *mot d'ordre* is rigid economy in State expenditure, and with regard to the latter the conditions are difficult, as the collectors of taxes being remunerated by a *pro rata* commission, their obvious aim is to extract all that is obtainable from the taxpayers.

One of the most vital questions which affects life at Naples is that of an adequate water supply, for drinking as well as for street watering and flushing, and from various causes there is a tendency to waste during the summer months, which makes the problem of street watering, with economy of the drinking supply, a question of considerable complication and difficulty. Many authorities besides the Socialist members of the Town Council advocate the municipilisation of the gas, water, and electric lighting undertakings, all of which, with the exception of the last named, are in the hands of foreign companies.

With regard to the housing of the working classes in Naples, there is still a great deficiency of accommodation, insomuch that the dwellings are drawn for by lot. Moreover, the rent of the rooms is found to be very high, which, with the cost of locomotion from the dwellings to the business centres, makes the total rent charge prohibitive. During 1913 labour at Naples asserted itself by striking for improvements, but sometimes these were on grounds apparently inadequate to justify the throwing into enforced idleness of large bodies of workmen dependent on daily earnings for a living and the consequent paralysing of public life. Recent strikes have, however, developed in the ordinary peace-loving Neapolitan a strong sense of rebellion against allowing the public services to be at the mercy of labour agitators. The teachings of these demagogues have driven, in some cases, employers to seek means of carrying on industries with a minimum of hired labour. Labour-saving machinery is thus displacing hand labour, which cannot always be relied upon. The installation of machinery in some cases has opened the eyes of the industrialist to the fact that he is now turning out a better product at a higher profit to himself, whilst paying his much reduced staff better salaries.

THE ENCOURAGEMENT OF CHINESE NATIVE TRADES IN SHENSI.

Shensi, one of the eighteen provinces of China proper, occupies an area of about 75,270 square miles in the north-western part of the country. It supports an estimated population of 8,500,000, of which number the greater part live in the south-eastern portion of the province, where are practically all of the important cities, including Sianfu, the capital. Owing to its geographical isolation, Shensi remains one of the least known provinces of China proper. Three purely native trades are taught at Shensi—weaving cotton rugs in the native fashion, weaving woollen Tientsin rugs, and making lacquer ware. Native cotton rugs are woven in a curious fashion. No loom is used, the warp being raised from the floor by brackets some thirty feet apart, between which it is stretched at a distance of a few inches above the ground. The rugs are woven in sections one foot wide and six feet long, five of such sections being woven in one piece. According to the United States Consul at Dalny, the operator squats across the warp, with the finished portion of the strip behind him, and moves a small stand, which separates the strands of the warp, along in front of him as he works.

The shuttle is thrown by hand from side to side. For the warp foreign imported thread is used, while for the woof native thread is found to be sufficiently good. A pattern is woven in, the right and left hand and middle sections being woven at different times, but with such a degree of accuracy that the figure of the pattern matches perfectly when the rug is assembled, which is accomplished by sewing together the four appropriate sections, making a rug six by four feet, closely woven and about the weight of a piece of heavy canvas.

All sorts of articles, from small pin boxes to heavy furniture, are manufactured in lacquer. For small articles a base of leather is used; this is wet, placed on a last of the desired shape, and pounded and ironed until it takes the shape of the mould and its edges adhere one to the other. The receptacle so formed is roughly coated with lacquer inside and out, further coats being added until the necessary degree of stiffness is secured. It is then hand-polished with wet charcoal until smooth, when the fine upper coats are applied. The number

of these depends on the quality and ornamentation desired, articles carved in heavy relief requiring many more coats than those bearing a plain polished surface. For the larger articles, such as furniture, trunks, etc., a wooden base is used. At the Provincial Industrial Exhibition held in Shensi, in celebration of the second anniversary of the Republic, a great variety of lacquer was on view, including a pair of very handsome Chinese wardrobes with panelled doors. These measured about six feet in height by five in breadth by one foot and a quarter in depth.

The third of the purely Chinese trades taught is the weaving of Tientsin rugs or carpets. The warp and woof of these are heavy cotton thread, generally of foreign origin, and the pile either camel's hair or wool. The warp is stretched vertically from a fixed support on the top over a roller at the bottom. The woof and the pile are put in by hand. Several workmen are engaged on the same rug at the same time, as each man can handle but five feet in width on the rug. The pile is applied by knotting woollen yarn loosely about the warp; the ends of the yarn are then cut roughly with a knife. The woof is next woven in about the last line of pile, and hammered down with a small wooden mallet. The pile is now trimmed to the desired length with shears, and the process repeated for each line of pile. When several feet of the rug have been completed, the finished portion is taken up over the roller at the bottom, the warp being adjusted at the same time on the fixed support above. Rugs are woven at the rate of a foot a day, the number of workmen on each rug depending on its width, as explained above. Most intricate patterns are woven with no guide for the workmen beyond their memories. The price of a rug depends on its quality, which is judged by the material employed and the number of strands of woof to the inch.

The above trades are taught in the Industrial Training Institute. There are in the institute about two hundred students, all drawn from the poorer classes, learning seven different trades. Apart from the master workmen, who are the actual instructors, there is a staff of fifteen directors and supervisors. The majority of the students are engaged in learning some form of the cotton spinning or weaving industry. The spinning is done on small foot-power machines, built locally in wood after the pattern of imported iron machines, each machine having twenty spindles. There are seven of these machines in use, each capable of spinning about three pounds of cotton per day. In the cloth and towel weaving industry there are about fifty students. As with the spinning machinery, the hand looms are copies in wood of foreign iron machines. The thread used is partly imported and partly of local origin. Turkish towels, very commonly coloured either pink or blue, and both coloured and figured cloth are woven. To this end a considerable part of the institute is given up to dyeing thread. The students in the institute receive no pay, but are given board and lodging. No apprenticeship fee is asked, as the intention is to draw the students from the poorer classes. The course is of three years, at the end of which time those who have qualified are in a position to earn from 12*s.* 6*d.* to 21*s.* per month, which is considered good pay in Shensi. Some of the students are retained at the institute as instructors, others secure positions as instructors in similar institutions in other parts of the province, while the majority are expected to find work with the general public.

ENGINEERING NOTES.

Sydney Harbour Bridge and Connecting Railways.—The great expansion of the trade of New South Wales and the fact that Sydney has already become the fifth port of the Empire have made it necessary to provide new facilities for its interna and suburban traffic. In fact, it is asserted that the streets of Sydney are more congested than those of London, where tube, motor-bus, and tramway development have kept pace with the requirements. In Sydney the main problem will be to link the north and south side of the harbour. The scheme which is to be brought before the New South Wales Parliament involves the construction of underground railways in the city itself, the electrification of the suburban lines, and the building of a large high-level bridge to connect the north and south side of the harbour. The city of Sydney is situated on the south side of the magnificent bay, and populous suburbs have risen on the north shore. The outlay for the whole project, comprising the erection of a large electric power station, is estimated at £17,000,000. In order not to obstruct the shipping, which aggregates more than 20,000 vessels annually, the bridge will have to cross on one clear span of 1,600 feet. By adopting gradients at each end of the bridge, a junction of the bridge railway with the underground system could be effected, and at the same time give the bridge a headway of 170 ft. at high water. This would clear the masts of all ships trading with Sydney. The rocky shore favours the construction of the bridge, and the Public Works Committee have decided on the cantilever type as being the most rigid and suitable for heavy traffic. Nickel steel is to be the chief material. The anchor arms are to be constructed on false-work and the cantilever arms are then to be erected, the suspended span being also built from both sides by the cantilever method. The greatest wind velocity recorded at Sydney was 120 miles per hour, and consequently a wind pressure of 50 lbs. per square inch is to be allowed for.

Remarkable Ferro-concrete Tunnel in America.—A most unusual piece of engineering construction is nearing completion at Baltimore. The work consists essentially of converting an old brick-lined water tunnel, in which the flow was by

gravity, into a pressure conduit operating under a head of 35 lbs. per square inch. The novelty lies in the use of huge separately moulded concrete pipes, the largest having a diameter of 9 ft., to form the new tunnel lining. As the existing tunnel is only 12 ft. in diameter, it is clear that the work had to be carried on in cramped quarters, and, in addition to the difficulties inherent in placing 10½-ton sections of pipe with so little working room, there is the obligation of shutting-down operations every few days and using the conduit to deliver water to the city. The valves are then closed and the tunnel drained in order to allow the work of lining to proceed. One of the features of the construction is a specially designed car, which carries the ponderous pipes into the tunnel and by means of adjusting equipment sends them accurately to line and grade. The concrete pipes are of particular interest, for they are claimed to rank amongst the largest precast units ever built. It is also unusual to use ferro-concrete to resist such a great internal pressure as is found in the Baltimore tunnel conduit.

Electric Canal Haulage.—The Harecastle Canal tunnel, constructed by Telford in 1827, has been worked by horse haulage until recently, when, owing to mining subsidences, the towing-path became inundated. The adoption of electric haulage presented some engineering difficulties, as, in consequence of the lowness of the tunnel roof, an overhead trolley wire could not be used. The North Staffordshire Railway Company have carried out a scheme in which a cable of four steel ropes has been laid through the tunnel, with an anchorage at each end, and the haulage boat is attached to this cable. The current cannot be conveyed direct from a generating station to the haulage boat, and the necessary supply of electricity is derived from accumulators carried in a special barge linked up with the hauling boat. The power is generated at a special station which has been erected at the Chatterley end of the tunnel. Each accumulator barge carries sufficient energy for several journeys, and whilst one is in service the accumulators of the other are filled at the generating station. The haulage barge is capable of pulling along seventeen loaded barges, each carrying twenty tons, and of accomplishing the journey through the tunnel in forty minutes.

The New System of Electro-percussive Welding.—This process adds another to those electric welding methods already existing. Arc welding has been very successful, and is effected by the intense heat of a direct-current arc with the aid of a suitable flux. Another method consists in passing a very heavy current through the metal pieces until the intense heat causes them to weld together. Alternating current is employed in this system, being more conveniently transformed to the very low voltage required. The new method is described in a paper by Messrs. C. E. Skinner and L. W. Chubb, presented at a recent meeting of the American Electro-Chemical Society. The paper states that in the process of electro-percussive welding two wires are welded together by causing a condenser discharge to pass between the ends of the wires at the moment when they are pressed together by mechanical force. The generation of the heat is so localised, so sudden, so intense, that there is no time for unequal heat conduction through the shanks of the wire, and the ends will be melted and even vaporised whether the melting-point is high or low. For this reason metals of different kinds can be welded together independently of their electrical resistance, melting-point or heat conductance. Any combination of metals which has ever been tried will weld together, but the joints will not be permanent with such combinations as aluminium and tin, or lead and iron. Electrically the weld is complete in 0·0012 second, and although 23 kilowatts are being dissipated between the ends of the wire at a certain instant the total energy used at the weld is about 0·00000123 kilowatt-hour, or enough to light an ordinary 50-watt 16 candle-power lamp for 0·09 second.

A Two-thousand Ton Forging Press.—Illustrations and notes in the *Engineer* describe a very ingeniously-designed hydraulic press which has recently been built by Davy Bros., Ltd., of Sheffield. This machine is to be used for slabbing and punching steel tyres with the minimum manual labour, which is its notable feature. With this object in view the machine is provided with an electric rotating gear, hydraulic sliding mechanism, and apparatus for mechanically manipulating the blanks or blooms throughout the entire process of slabbing and punching. The revolving anvil, operated by an electric motor, is mounted on a sliding-table which is caused to move backwards or forwards on a machined slide on the bed by hydraulic power. This arrangement enables the blank to be withdrawn clear of the press to facilitate the handling of the work, and allows it to be lifted direct by the crane without having to pass it between the upright columns of the press. The arrangement is such that the rotating and sliding motions can be carried out simultaneously. To avoid frequently starting and stopping the electric motor it is run continuously, a slipping clutch allowing the table to stop when the forging is under the grip of the press, the rotation continuing directly the pressure is removed, a large amount of time also being saved in this way. With the exception of the rotating gear, all other movements are made by hydraulic power. When punching, the hole is partly made from the top and then the punching of the hole is completed in an upward direction, thus avoiding the formation of a fin. Beyond bringing and taking the blooms away, the whole sequence of operations is carried out under the press without any manual labour whatever.

An All-metal Diving Dress.—After experiments extending over five years the metal diving dress for deep-water diving has now reached a practical stage, and, it is claimed, will warrant its employment for a difficult job of off-shore salvage in waters too deep and too exposed for the use of the ordinary diving outfit. The *Engineer* in describing this invention states that in principle it is not strictly a novelty, because others have worked towards the same solution of a deep-diving apparatus; but this American dress is said to be the most feasible and efficient of these various efforts. During some demonstrations divers have used this armour at a maximum depth of 212 ft., but could have gone deeper had more water been available, and these submergences have proved extremely suggestive when viewed in the light of the circumstances under which they were made. The limitations peculiar to the elastic diving dress are directly overcome by the all-metal dress. The suit consists of a series of articulated sections having sliding or rotating joints, and these are sealed sufficiently by means of leather and rubber packing so that they may be either entirely water-tight or nearly so. There are fifty-six of these flexible joints. Mr. Chester Macduffee, the inventor of the dress in question, has designed his suit so that it is strong enough to withstand the crushing force of the sea without having recourse to air pressure within. The success achieved depends partly on the use of a suitable aluminium alloy. The diver breathes air at atmospheric pressure no matter how deep he goes. A hand-lamp is attached to the end of the left sleeve and may be supplanted by a hook. The right sleeve terminates in a mechanical hand composed of twelve steel fingers which are actuated by a sliding rod drawn inward through a stuffing-box by the simple act of gripping on the part of the diver. This new apparatus opens the way for certain salvage operations and deep-water explorations which otherwise would be out of the question, as the weather conditions and the tidal circumstances which hamper so much the man in the elastic dress would not place the same hindrances in the way of the diver clothed in the rigid outfit.

CORRESPONDENCE.

THE INDIAN INDIGO INDUSTRY.

Margin for an Improved Process of Manufacture.

I have noted with great interest Dr. Mollwo Perkin's views as to the probable loss of 50 per cent. of the dye during manufacture as against the estimated 15 per cent. which we were led to believe takes place. This higher estimate, to my mind, makes all the difference when considering the advisability of further research work with a view to the possible development of a scientific method of extracting the dye, as indeed has been recently successfully accomplished in the case of the extraction of quinine from cinchona bark, an industry worked in Bengal by the Government of India.

In my opinion, an alternative method of extracting the dye is most necessary, and should conform to Professor Meldola's scientific suggestion put forward in his paper published in *Nature*, July, 1908; and I believe if a process could be devised in which all the leaves under treatment were simultaneously, uniformly, rapidly, and fully extracted, a much higher yield and a purer product would be obtained.

At present, under our actual working conditions, I think the degradation of the plant-extract is far more rapid and extensive than is estimated by the results of laboratory experiments, and consequently the loss mentioned by Dr. Perkin may even be exceeded.

If very rapid, complete, and uniform extraction could be obtained, I hold the view that this heavy loss would, in part at any rate, be avoided, and to make the advisability (in my opinion) of further research work clear, I will put the probable loss, as given by the author, into sterling values.

An average Behar indigo concern used to turn out about 1,000 maunds of indigo in an average season, the gross value of which, at 4s. per lb., amounts to £14,500, and if the outturn was only 50 per cent. of the possible, it is evident that a loss of £14,500 was taking place! This would seem to justify a further effort being made to put the industry in a position to compete with its artificial rivals in future.

Future Competition.

I note the remarks made with regard to this point in the discussion, and it seems to me that it remains to be seen at what cost synthetic indigotin, aniline and alizarine dyes can be produced at and sold here, and also in Germany, after the war. The Germans never disclosed their costs of production of synthetic indigotin, and the firms interested may have been losing in this department of their enormous businesses, hoping to recoup themselves by a world's monopoly later on.

It seems to me that in the past—1897 to October, 1913—they had the benefit of a very cheap supply of commercial benzol, from which aniline is produced, and which is, therefore, the raw material in one of the processes for the manufacture of synthetic indigo.

This period of cheap benzol appears to have ended about the above date owing to the rapid advance in the price of petrol—benzol as a substitute increasing in price—and it seems to me that the price of the latter is not likely to fall, especially when Britain and Germany come into future competition for it for motor fuel and the raw material of their artificial dyes. If I am right in this view, it would seem as if natural indigo might possibly benefit.

Dye Vat Tests.

I would like to mention that no authoritative tests to ascertain the real dyeing values of indigo and synthetic indigotin have ever taken place, and

I hope prominence will be given to this fact, and that proper trials will be made to decide once and for all their actual dyeing strengths, and consequently the real values, of these two rival dyes.

LEWIS J. E. HAY.

42, Frederick Street,
Edinburgh.

OBITUARY.

CHARLES EDWARD CHRIMES.—Mr. Charles Edward Chrimes, who died on November 28th last at the age of seventy-five, was the surviving principal of the firm of Guest & Chrimes, foundry and general brass works, Rotherham. For over sixty years he had been associated with the firm of which he eventually became the head, and it was generally due to his efforts that the house of Messrs. Guest & Chrimes attained its present reputation.

He was naturally of a retiring disposition, taking no active part in public matters, and what services he rendered in this direction were given in a quiet way, as were his benefactions to local institutions, which were considerable. The greater part of his time was devoted to business and care for his workers, the fact that so many men having been employed by the firm during the whole of their working career being a testimonial to his management, kindness, and generosity.

Mr. Chrimes was elected a member of the Royal Society of Arts in 1897.

NOTES ON BOOKS.

RAILWAY RATES AND TRAFFIC. Translated from C. Colson's "Transports et Tarifs." By Charles Travis. London: G. Bell and Sons. 3s. 6*d*. net.

The authors, for Messrs. Christie and Leedam were associated with Mr. Travis in the work of translation, have selected from a well-known French authority those portions of his book which they consider most suitable for English readers, and it may be assumed that their method was judicious, though Mr. W. M. Acworth, who contributes a brief introduction, regrets that it was not found practicable to translate the whole book as it stands. The French, after their wont, have dealt with the whole question of transportations, tariffs cost, and administration, in a more logical and scientific manner than we have ever attempted, and though M. Colson has naturally treated his subject as applied to French methods, the general principles are applicable to all countries. The book is, therefore, one that can be commended to all students of railway economics, and indeed to all students of economics. It is divided into four parts. Part I. deals with the economic considerations which determine the cost of transportation; Part II. with railway rates in France; Part III. with rates in Europe and America; while Part IV. is devoted to the author's general conclusions.

GENERAL NOTES.

CHADWICK PUBLIC LECTURES.—A course of three lectures (illustrated by lantern-slides) on "War and Disease" (1. Continental Wars of the Nineteenth Century; 2. The South African and Russo-Japanese Campaigns; 3. The Great European War), by F. M. Sandwith, Esq., M.D., F.R.C.P., Gresham Professor of Physic; Senior Physician, Albert Dock Hospital, and London School of Tropical Medicine; Chairman of the County of London Branch of the British Red Cross Society; formerly Senior Physician, Imperial Yeomanry Hospital, South African Field Force, will be delivered on Fridays, January 15th, 22nd, and 29th, 1915, at 5.15 p.m., at the Royal Society of Arts, John Street, Adelphi, W.C. The chair will be taken on January 15th by Sir William J. Collins, K.C.V.O., M.D., M.S., B.Sc., Chairman of the Chadwick Trustees; January 22nd by Sir Frederick Treves, Bart., G.C.V.O., C.B., F.R.C.S.; January 29th by Sir Henry Trueman Wood, M.A.

THE ANNUAL OF ART WORK.—The first number of this annual, which is a supplement to the *Art Workers' Quarterly*, has just been issued under the editorship of Mr. W. G. Paulson Townsend. It contains, among other things, articles on the Relation between Trade and Art, by Mr. Frank Stuart Murray; the English Home, by Mr. C. F. A. Voysey; Water-Colour Hand-Prints, by Mr. W. Giles; Technical Education and Industrial Art, by Mr. Arthur Wilcock; and an excellent article by the late Mr. Lewis F. Day, on the Designer and his Trade, which was originally written for members of the Design Club. Although the subjects dealt with are naturally very various, throughout the whole annual one theme is generally insisted upon—the dependence of our industries upon artistic qualities for their success. The annual is well printed on good stout paper, and the numerous illustrations are admirably reproduced.

INDIAN, CEYLON, AND JAVA TEA IN 1914.—The most remarkable feature of the tea market during the year just ended was the sustained demand in spite of the outbreak of war and its attendant disturbing influences. The year opened with a very strong position, duty payments for 1913 having increased by some 10,000,000 lbs. over 1912, and consumption per head of population having advanced from 6·46 lbs. to 6·61 lbs. A very satisfactory level of price has been maintained throughout 1914, especially for useful common and lower medium sorts; any considerable decline, such as that which occurred towards the end of September, being only of short duration. During the latter half of the year, the outbreak of war in Europe and the interference with shipments both from India and Ceylon made market conditions entirely abnormal; an extensive demand from near continental countries (combined with smaller offerings at a period when the trade is usually fully supplied)

resulted in a very considerable rise in prices, especially for leaf descriptions, and during the first week of November clean common leaf touched the high level of 9¼*d*., a figure not reached since June, 1891. The stringent regulations as to exports to Holland, Norway, Sweden, and Denmark, made on November 17th, at once caused a sharp reaction; prices gave way for some of the better leaf kinds as much as 1*d*. to 1½*d*. per lb. within a week, whilst the increase of the duty from 5*d*. to 8*d*. also brought about a quieter demand for finer and tippy descriptions; on the whole the market has been in favour of producers, and the prices realised by the majority of them can be considered as quite satisfactory. Imports of all tea to the United Kingdom for the year were smaller, being 344,750,000 lbs., against 366,023,125 lbs. in 1913, whilst deliveries both for the home trade and exports were considerably larger, and stocks at December 31st show a large decrease. Therefore, from a statistical point of view, the position at the moment is very encouraging.

METAL BEDS IN BRAZIL. — The metal-bed industry in Brazil is rapidly increasing in importance, and although this country possesses an abundance of splendid hardwoods suitable for furniture making, they are very expensive, and metal beds can be manufactured much more cheaply, and consequently are growing more popular. All the materials used in the manufacture of these products, such as tubings, casters, wire springs, knobs, etc., are almost entirely coming from England. The greatest demand is for iron tubing of various diameters, suitable for different beds, ranging from those for infants to double beds for adults. The cutting in proper lengths, bending, and painting are all done in Brazil. Most of the brass bedsteads now being sold, and the number is limited, are imported already made complete.

COTTON FOR PAPER.—The *Paper Makers' Monthly Journal* tells of an enterprising American cotton manufacturer who has been sending out to his customers a sample letter printed on cotton goods. The text of the letter reads as follows: "While not made primarily for that purpose, you will see that the material on which this letter is written answers quite well for that purpose, and also, as shown, makes a satisfactory carbon copy. If desired, of course, it could be made even a little stiffer yet. The cost of this exact fabric and finish figures out about 3 dols. per thousand sheets unprinted, whereas the unprinted sheets we use of paper costs us 2.50 dols. per thousand. We do not claim that this cloth should be used permanently in place of paper, but merely claim for it something of a novelty while about half the population of this country seems to be crazy on the subject of finding some use for the surplus cotton." It is claimed that it would be exceedingly useful for advertising purposes. It works very well on a typewriter and makes excellent carbon copies.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 20.—J. A. HUNTER, "The Textile Industries of Great Britain and of Germany." LORD ROTHERHAM, President of the Textile Institute, will preside.

JANUARY 27.—HON. JOHN COLLIER, R.O.I., "Portrait Painting." LORD SANDERSON, G.C.B., K.C.M.G., will preside.

FEBRUARY 3. — OCTAVIUS CHARLES BEALE, Chairman of the Australian Manufacturers' Association, "Imperial Industrial Development after the War."

FEBRUARY 10.—F. VINCENT BROOKS, "British Lithography in 1915."

FEBRUARY 17.—ARTHUR WILCOCK, "Decorative Textiles, and the Designer's Relation to the Industry."

FEBRUARY 24.—W. J. ASHLEY, M.A., M.Com., Ph.D., Professor of Commerce in the University of Birmingham, "The Economics of the War."

MARCH 3.—WILLIAM POEL, "Shakespeare's Profession."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 21.—HENRY JOHN ELWES, F.R.S., "Nepal." The RIGHT HON. SIR HERBERT MAXWELL, Bt., F.R.S., will preside.

FEBRUARY 11. — CAPTAIN SIR GEORGE DUFF DUNBAR, Bt., I.A., "Tribes of the Brahmaputra Valley." LIEUT.-COLONEL SIR FRANCIS YOUNGHUSBAND, K.C.I.E., LL.D., D.Sc., will preside.

MARCH 18. — LIEUT.-COLONEL A. C. YATE, I.A. (retired), "The Indian Army."

APRIL 15.—M. M. S. GUBBAY, I.C.S., "Indian Trade and the War."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 26. — MAJOR E. H. M. LEGGETT, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda."

FEBRUARY 2.—EDWARD R. DAVSON, "Sugar and the War."

MAY 4.—S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced:—

THOMAS WORTHINGTON, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. Thorne Baker, "The Industrial Uses of Radium."

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. Hulme, "Patent Law."

H. M. Thornton, "The Industrial Uses of Coal Gas."

D. Y. Cameron, A.R.A., R.E., "Etching."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

A. S. E. Ackermann, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

Lady Lugard, "The Work of the War Refugees' Committee."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Indian Section.

Thursday afternoons, at 4.30 o'clock :—

April 15, May 13.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock :—

March 2, 30.

Cantor Lectures.

Monday evenings, at 8 o'clock :—

F. Mollwo Perkin, Ph.D., F.I.C., F.C.S., M.Inst.P.Tech., "Oils, their Production and Manufacture." Three Lectures.

Syllabus.

Lecture I.—January 18.—Mineral oils—Historical — Their sources — Oil-fields and their distribution — The production and refining of natural mineral oils—The shale-oil industry and its possibilities.

Lecture II. — January 25. — Low temperature carbonisation—cracking of oils—Motor spirit—Fuel oils.

Lecture III.—February 1.—Vegetable oils—Raw materials—Sources of supply—Methods of manufacture—Methods of refining—Edible oils—paint oils.

M. H. Baillie Scott, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Fothergill Lectures.

Monday evenings, at 8 o'clock :—

Professor Vivian B. Lewes, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

February 15, 22, March 1.

Juvenile Lecture.

Wednesday afternoon, at 5 o'clock :—

H. Plunket Greene, "How to Sing a Song." Two lectures, with vocal illustrations.

January 13.

MEETINGS FOR THE ENSUING WEEK.

Monday, January 11...Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 3.30 p.m. (Juvenile Lecture.) H.H. the Ranee of Sarawak, "Sarawak and its People."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. L. O. Matthew's paper, "The Report of the Land Enquiry Committee on the Acquisition of Land."

Geographical Society, Burlington Gardens, W., 8.30 p.m. Mr. H. Raeburn, "The Adai Group of the Caucasus."

Tuesday, January 12...Asiatic Society, 22, Albemarle-street, W., 4 p.m. Lieut.-Colonel P. M. Sykes, "The History of Persia."

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. Mr. A. L. Bell, "The Lateral Pressure and Resistance of Clay, and the Supporting Power of Clay Foundations."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Dr. S. P. Smith and Mr. R. S. H. Boulding, "The Shape of the Pressure Wave in Electrical Machinery."

(Scottish Section.) Princes-street Station Hotel, Edinburgh, 8 p.m. Mr. C. J. Beaver, "Cables."

Wednesday, January 13..Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lecture.) Mr. H. Plunket Greene, "How to Sing a Song." (Lecture II.)

Electrical Engineers, Institution of (Yorkshire Section), Philosophical Hall, Leeds, 7 p.m. Mr. E. B. Wedmore, "Automatic Protective Switchgear for Alternating-current Systems"

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. T. Clarkson, "Wheels for Commercial Motors."

Literature, Royal Society of, 20, Hanover-square, W., 5.15 p.m. Professor Sir Henry Newbolt, "Shakespeare's Non-Historical Plays."

Thursday, January 14 . Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. H. Selby, "Rambles in Donegal."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Dr. S. P. Smith and Mr. R. S. H. Boulding, "The Shape of the Pressure Wave in Electrical Machinery."

Friday, January 15...Chadwick Public Lectures, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.15 p.m. Dr. F. M. Sandwith, "War and Disease." (Lecture I.)

Offer of Set of Journals.—A Fellow of the Society offers to present a complete set of the *Journal of the Royal Society of Arts*, from 1882 to the present date, to any Library which would care to accept them. The numbers are unbound.

Journal of the Royal Society of Arts.

No. 3,243. VOL. LXIII.

FRIDAY, JANUARY 15, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 18th, 8 p.m. (Cantor Lecture.) F. MOLLWO PERKIN, Ph.D., F.I.C., F.C.S., M.Inst.P.Tech., "Oils, their Production and Manufacture." (Lecture I.)

WEDNESDAY, JANUARY 20th, 8 p.m. (Ordinary Meeting.) J. A. HUNTER, "The Textile Industries of Great Britain and of Germany." LORD ROTHERHAM, President of the Textile Institute, will preside.

THURSDAY, JANUARY 21st, 4.30 p.m. (Indian Section.) HENRY JOHN ELWES, F.R.S., "Nepal." The RIGHT HON. SIR HERBERT MAXWELL, Bt., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

On Wednesday afternoon, January 13th, Mr. H. PLUNKET GREENE delivered the second and concluding lecture of his course on "How to Sing a Song."

He began by recapitulating the principal points of his first lecture, and insisted especially on the importance of imagination in a singer. In addition to the points mentioned last week as being necessary to a singer, Mr. Plunket Greene desired to add one more—style. It was difficult to define style, but an idea of it might be derived from the old tag, *Ars est celare artem*, which might be freely rendered, "Do not give the show away."

The first lecture was devoted to considering how to sing; that day the lecturer proposed to deal with the songs which a singer could sing. Songs were of two classes—those in which the voice was used simply as a musical instrument, and those in which the words were the important thing. The latter were by far the most interesting to sing as the singer could be dramatic. Out of every hundred songs, said the lecturer, ninety-five belonged to the first class.

A very large number of songs deal with the supernatural, fairies, ghosts, witches, and so forth, *e.g.*, among the songs which he was going to sing the first three were supernatural, and this though the songs had been chosen without any regard to this point.

In illustration of the various points discussed in the lecture, Mr. Plunket Greene then sang the following songs:—

	Atmospheric.	
1	The Fairy Lough . . .	C. V. Stanford
	Dramatic.	
2	The Erl-King	Schubert
3	Scared	C. V. Stanford
	Narrative.	
4	The Twa Sisters o' Binnorie (Old Scotch Ballad)	*Arranged by* Arthur Somervell
	Characterisation.	
5	Autolycus' Song . . .	H. Walford Davies
	Reminiscence.	
6	When Childher Plays .	H. Walford Davies
	Contemplative.	
7	Drake's Drum	C. V. Stanford
	Address or Ode Songs.	
8	Daddy-Long-Legs . .	C. V. Stanford
	Bel Canto and Rhythmical.	
9	(*a*) Boat Song . . .	C. V. Stanford
	(*b*) Trottin' to the Fair (Old Irish)	*Arranged by* C. V. Stanford
	Ghost.	
10	The Twa Sisters o' Binnorie (Old Scotch Ballad)	*As above*
	Question and Answer.	
11	(*a*) The City Child . .	C. V. Stanford
	(*b*) Mary	A. M. Goodhart
	Humorous.	
12	The Crocodile (Old English)	*Arranged by* Lucy Broadwood

At the conclusion of the lecture the Chairman said that from what had been said about magnetism — by which was really meant sympathy between the lecturer and his audience —it must be quite obvious to Mr. Plunket Greene that they had greatly enjoyed his lectures. He would therefore content himself with moving a hearty vote of thanks to the lecturer for his interesting course, and to Mr. S. Liddle, whose brilliant accompaniments had added so much charm to the illustrative songs.

The vote of thanks was unanimously carried, and the meeting terminated.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE HISTORY AND PRACTICE OF THE ART OF PRINTING.

By R. A. PEDDIE,
Librarian, St. Bride Foundation Typographical Library.

Lecture IV.—Delivered December 14th, 1914.

The recent history of colour printing is divided easily into two sections—non-photographic and photographic. Each section comprises three methods — intaglio, relief, and planographic, so that the subject is comprised in these main headings :—

NON-PHOTOGRAPHIC.

Intaglio.—Etchings and copperplate prints of all kinds, in colour.

Relief.—Chromo-Xylography.

Planographic.—Chromo-Lithography.

PHOTOGRAPHIC.

Intaglio.—Photogravure.

Relief.—Half-tone.

Planographic.—Photo-Chromo-Lithography, Chromo-Collotype.

Doubtful and combination processes, of course, add to the number.

CHROMO-LITHOGRAPHY.

The period I am dealing with in this lecture begins with the rise of chromo-lithography.

By 1850 the problem of the super-imposition of colours had been solved, and the art started on its triumphal course. In 1856–57 Lemercier, of Paris, printed an edition of the "Imitatio Christi" for which illuminated borders were copied from early manuscripts, and every page was decorated. In England, Owen Jones was working on his "Grammar of Ornament." It was printed by Day & Son, who were at this time the leading chromo-lithographers in London.

The most important non-commercial application of chromo-lithography was begun in 1856 by the Arundel Society, which issued prints of Italian frescoes until quite recent years. They were not all printed in England, some well-known German firms producing many of the later prints.

The "oleograph," a rather distressing form of the chromo-lithograph, was of German origin The finished print was thickly coated with varnish and then passed between patterned rollers giving the impression of canvas.

In the early days of chromo-litho work, the prints were frequently produced on thin paper. After printing, the margins were cut off and the print mounted on thicker paper, or, in the case of book illustration, mounted on the pages left for them. In several cases of books in the early fifties, spaces were left for illustrations to be mounted on the same pages as the text.

The method of chromo-lithography is shown very well in Audsley's book on the subject. The object—say, a water-colour drawing—is dissected by the litho artist into the number of separate tints required for its reproduction. A key plate in black is produced, and as many pulls taken as the number of printings required. The part of the design to be printed in each colour or tint is then transferred to a separate stone. The series of progressive proofs in Audsley's book shows how a picture is built up by the successive printings.

The history of chromo-lithography during the last sixty years (except in its association with one or other of the photographic processes, which is dealt with later) is a history of technical improvements rather than of revolutionary change. Better work can be done and is done to-day than at any previous period, owing to these improvements in ink, paper, and machines. Photography has, no doubt, closed many doors to chromo-litho work, but there are many fields in which it retains its supremacy. Artists have turned their attention to it in recent years, and many auto-chromo-lithos have been produced. The style found to harmonise best with the process is curiously similar to the plates in the first book printed by Hullmandel by his chromo-lithographic method. It is possible that there are greater artistic developments ahead for this method of work.

The offset machine which I described in the third lecture has been adapted for colour work. Here its ability to print on any surface paper is of exceptional value, and the softness of the colouring of some offset productions is very effective.

COPPERPLATE PRINTING IN COLOURS.

Intaglio plates—that is, mezzotints, stipples, and line engravings—are printed in colours to-day in exactly the same way as in the eighteenth century. The plate is inked by hand with all the colours necessary—practically painted—and the whole printed at one impression. The modern development described as colour etching has various exponents. By some the plate is printed twice, first for the broad masses of colour, and secondly for the actual lines of the

etching. The specimens shown by Hugh Paton and V. Preisler sufficiently indicate the scope and method of this process.

Wood-block Colour Printing.

In relief printing the most interesting process after 1850 is wood-block colour printing. This process, where separate blocks are used for each colour, gives an impression of transparency which cannot be obtained by any other.

This method of colour work was carried to a considerable pitch of excellence by Savage about 1820, and it was probably after seeing his work that Thomas Bewick suggested the printing of pictures in colours by means of wood-blocks. It was not, however, until about 1850 that wood-block printing became at all common.

The two most effective English workers in chromo-xylography were Edmund Evans and Benjamin Fawcett. The latter is a striking instance of unaided genius working alone and producing effective work. His illustrations to Morris's "British Birds" will alone suffice to keep his name in the annals of great colour printers. The book illustrations of Edmund Evans are, perhaps, the best examples of pure wood-block colour work carried out in this country.

The most typical works of Evans in later years have been the books of Walter Crane, Kate Greenaway, and Randolph Caldecott, specimens of whose works are on show, together with some earlier productions for the purpose of comparison.

Chromo-xylography is not prominent in the colour work of the Continental printers. But there is one exception. The firm of Knöfler, of Vienna, founded about 1856, has produced work of the highest character by this process. Religious prints of all kinds have been their speciality, and the transparency of the colours and the general beauty of their work give the firm a very high place among colour printers.

Miscellaneous Methods.

There are a few processes of colour printing which do not quite come under any of the headings I have adopted, and these I propose to take, perhaps out of their order, so that the latter part of my lecture can be devoted to the photographic processes. An important machine in this class is the Orloff. This is the invention of a Russian engineer, and is used in the State Printing Office at Petrograd for printing bank notes and similar colour work. The method of printing is quite different from any other. On a large cylinder are fastened the various printing blocks, one for each colour. A series of inking devices apply the correct colour to each block as the cylinder revolves. These blocks transfer their colours to composition rollers, which in turn apply it to the "form" block. All the colours are by this means superimposed on this form block, which then comes in contact with the paper and deposits the whole of the colours at one impression. It might be imagined that this process of superimposition of wet colours would cause smudging or blurring, but work produced by the Orloff press is noticeable for clearness of outline and delicacy of detail. The machine has been put on the English market once or twice, but has never been adopted.

Another recent process of interest is stencilling by machine. This method has been considerably used for roughly colouring plates. It has now been made possible to stencil by machine, Orsoni's Aquatype having been invented in 1898 and since perfected. The sheets or prints to be coloured are fed on to a travelling band, which carries them in turn under as many stencils as there are colours to be applied, when another portion of the mechanism passes a colour brush over the stencil then in position on the sheet. Some of the French fashion papers have their plates tinted by this machine, which is also extensively used for picture postcards.

Photographic Processes.

The whole of the photographic colour processes may be divided into two series. The first includes all those in which the photograph is merely the basic plate or outline, and the colours are selected by eye and printed over it. Postcards, for instance, are frequently printed with a collotype basis and lithographic colouring. As far back as 1858 Geo. Baxter patented a method of colouring photographic prints lithographically. These combinations are too numerous to mention.

Photogravure.

Photogravure plates are frequently printed from in colour by the old eighteenth-century method of inking the plate with all the colours and printing at one impression. The facsimiles of the paintings of G. F. Watts have been produced by Messrs. Emery Walker in this manner. Before leaving photogravure it must be mentioned that constant attempts have been made to print photogravures in colour by machine. This process has been adapted to fast rotary printing in monochrome, and flat

bed machine photogravure is common; but with the exception of a few experiments, machine-printed photogravure in colours belongs to the history of the future, and is therefore outside the scope of this paper.

There is, however, one process which has not yet been made public that I may refer to. This is a combination of the intaglio and offset methods, and the experimental prints have been made by Mr. Geo. W. Jones. The machine is called the Renaissance, and is made by Linotype & Machinery, Ltd. Instead of a copper cylinder, as in the ordinary photogravure machines, a strip or sheet of copper is used, and the picture etched on the flat sheet, which is then bent round the cylinder. The wiping is done with rollers instead of the ordinary steel knife, and the impression is taken on a rubber cylinder, which transfers it to the paper. The first experiment made in colour on this machine was a reversed half-tone three-colour, but later photogravure negatives have been used with very effective results. A high-grade softness of colour is produced, and the high lights are better cleaned than with the pure photogravure method. It will be very interesting to see the later work of this machine. The colour prints by the Rembrandt Intaglio Engraving Co. in two and three printings are by a secret photogravure process.

Three-colour Process.

I now have to deal with the three-colour process, and describe how the automatic selection of colour was invented and developed. The idea of three-colour printing was not new, having been used by Le Blon in the eighteenth century. His ideas were based on the investigations of Sir Isaac Newton. Further researches in the early part of the nineteenth century by Dr. Thomas Young led him to put forward the theory of three primary colour sensations; but until Helmholtz revived it in 1853 it had been shelved. In 1860 Clerk Maxwell made a complete study of the subject, with the result that in 1861 he was able to take three photographs of a piece of coloured ribbon through three coloured light filters. By superimposing the three images obtained, and projecting them in an optical lantern through the three filters, he obtained a coloured image of the ribbon. This image was not perfect, owing to the fact that photographic plates were not at that time sensitive to red and green. It was suggested, very shortly after, to apply the principle to colour printing, but the photographic plate difficulty was not removed until 1873, and then only partially, while the complete discovery of the principle of colour sensitive plates did not come about until the early eighties. Dr. E. Vogel in Germany, and Mr. F. E. Ives in America, were proceeding on very similar lines. Mr. Ives had already invented the cross-line screen, and it is owing to his researches that the three-colour block process became possible.

He exhibited at the Philadelphia Exhibition of 1885 prints made by this process, but thought so little of it that he did not trouble to patent it. At that time the colour filters and the half-tone screens were comparatively imperfect, and commercial work was still some distance off. Not until 1891 was any commercial work put forward, and in the latter part of this year several English firms took the process up. One of the first three-colour prints produced in this country was a plate representing the famous racehorse that won the Derby in 1890. This was produced by Messrs. Waterlow & Son in February, 1892, as a supplement to the paper *Land and Water*. The improvements in the process that have taken place since that time are purely technical, the character of the process remaining the same.

The technical description of the process which follows is taken from Gen. Waterhouse's introduction to the catalogue of the photo-engraving exhibition at South Kensington:—

"The problem to be solved in photographic three-colour printing is a complicated one, because the light reflected from the objects to be reproduced must first be analysed and divided into its three components, red, green, and blue-violet, by means of carefully selected coloured screens or filters, so that each of them may impress a negative image, or colour-record, upon three suitably sensitised photographic plates of the parts of the object containing it, the densities of the three images being proportionate to the quantity of each light passing through the screens and its luminosity. These three images must correspond exactly in size, so that they may register correctly.

"From these three colour-sensation negatives, positive prints are made suitable for the process selected, whether by superposition of transparent films, collotype or block printing, and must be printed in three colours or pigments, complementary to the filters used, viz., cyan-blue for the red sensation negative, crimson for the green, and yellow for the blue-violet.

"The correct combination of these three should reproduce the colours of the original.

Owing to the difficulty of obtaining suitable permanent pigments to meet the theoretical requirements in three-colour block printing, some workers add a fourth block printed in grey or black, to give strength and harmonise the colours. The greatest care has to be taken throughout in the proper selection and adjustment of filters, photographic plates and printing colours. The least divergence throws out the balance and produces a false effect.

"Practically it means the mutual adjustment of at least three different sets of three variable factors with almost mathematical accuracy. The printing processes are still imperfect, but the discovery of new sensitisers for the photographic plates, and fuller researches into theory and practice, are bringing about constant improvements, and it seems likely that before long their use will be greatly extended."

The method of photographic colour selection can be and is applied to the other photographic processes, but not yet to anything like the same extent as to the half-tone process.

The improvement in printing due to the introduction of more perfect machinery has had a considerable influence on the three-colour process. The two-revolution type of machine, such as the Miehle or Century, was found to give better register and possess more inking power, which has helped the process. Then, too, the platen press has of late years improved in strength of impression and inking power, which has enabled it to be used for colour work. The question of the ink is a serious one. It has improved in quality and in accuracy of tint, but the permanency of the colours still leaves much to be desired.

Several machines for simultaneous printing of colours have been invented. With the exception of the Orloff already mentioned, none appear to have survived. The Miehle machine has been adapted for continuous colour printing by joining three machines together by means of a special delivery apparatus, so that when the sheet leaves one machine it passes to the next, and so to the third.

The four-colour process is described in the following extract from Mr. W. Gamble's article on "Modern Colour Processes":—

"Whether to use three or four colours has long been one of the contested points in colour work. The theoretical advocates of three colours have stoutly held out for three-colour; but many practical men hold the faith that three colours can never give an entirely satisfactory rendering of the subject. The weakness of the three-colour process is chiefly found in the rendering of blue in all its gradations, in its inability to yield a good grey, and in the imperfection of the blacks, which, according to theory, should be formed by the superposing of the three colours in equal strength. The remedy proposed is to use a black or neutral grey as a fourth printing. Dr. Albert advocated this in his citochrome process, and many leading Continental workers have followed him. In America a firm known as the Quadricolour Company make it a rule to use four colours, and do admirable work. It is, indeed, quite general in America to find four-colour being given the preference to three, especially in blocks produced by hand processes. In England, though four-colour work is not so general, a fourth printing in black is often resorted to, or one of the trichromatic colours is run twice through to get increased strength.

"An interesting attempt to found a four-colour system of colour printing was the complementary colour process of Mr. C. G. Zander, which was patented in 1905. The inventor assumed that it was necessary to use, not three but four fundamental colours, viz., red, yellow, green, and blue, by mixtures of which in suitable proportions any colours in Nature could be matched or produced. The hues of these four fundamental (or monochromatic) colours may in popular terms be described as magenta red, lemon yellow, emerald green, and ultramarine blue. The four colours were grouped into two pairs of complementary colours, viz., red and green, yellow and blue, so that when the elements of either pair were mechanically mixed as pigments, by printing or staining they produced black. At first sight it might seem that the only difference from the ordinary process was the addition of a green printing colour, but actually the other colours have been scientifically adjusted or readjusted, so that they form two pairs of complementary colours. The author of this process claimed that practically the whole range of the spectrum colours could be produced by it, besides extra-spectral purples, dense pure black, and homogeneous greys. Mr. Zander asserts that no pure black can be reproduced at all in three-colour printing, whilst by his new process either of the two pairs would produce black or grey. Several specimens were produced by this process, and it certainly appeared capable of rendering more brilliantly the bright colours of flowers, ribbons, etc.; but the results were not entirely convincing, probably through

the engravers not having sufficient practice with the new method. Printers did not view with favour the idea of a fourth printing, and on the whole the process was received so coldly that the inventor has not pushed it further."

Collotype

Experiments with a view to using the collotype process for colour printing were made by Albert in Munich and Husnik of Prague in the early 'seventies, and the State Paper Office in Petrograd was producing colour collotypes by 1878. H. W. Vogel introduced colour-sensitive photographic plates about this time, and prints in collotype by this means were extensively made in Germany in the late eighties. Several firms in England adopted the process about 1890, among them Messrs. Waterlow & Sons. In 1890–91 this firm produced some very excellent work, but the process was not suitable for the English climate, and the introduction of the three-colour half-tone resulted in its abandonment as far as rapid commercial work was concerned. Of recent years collotype colour work has again come to the front, principally on the Continent, although a few English firms have done very well with the process. Messrs. Emery Walker have produced some very fine specimens of collotype in colours, which I am able to show.

During this survey of the recent history of colour printing, we see in the first period the rise of chromo-lithography and its only rival, chromo-xylography. With the exception of a few experiments, these two methods hold their own until the coming of three-colour work about 1890. The triumphal march of the three-colour process, with its accompanying disadvantages of clay-coated paper and fugitive inks, still continues, but there are signs of improvement. The development of the litho offset and photogravure processes are all for the betterment of colour work. The same disadvantages do not apply to them, and so there is a hope that we may presently have a process of colour reproduction that will be accurate, cheap, printed in fast colours, and on paper that will not fall to pieces after a few years or turn into a clay brick if it gets damp.

[Note.—Each lecture was illustrated by lantern-slides and an exhibition of specimens of printing. The exhibits were individually described after the lecture.]

THE UTILISATION OF PEAT IN ITALY.*

Several of the more important peat beds in Italy have been worked chiefly with a view of utilising the peat as fuel. Most of the peat is, however, too poor to compete with imported coal; hence the lack of success of all such undertakings even where they were connected with land reclamation schemes. Attempts have also been made to use peat for other purposes, such as litter, packing and isolating material, etc., but the quantities thus used are too insignificant to be of any economic importance. Of late, however, the nitrogen contained in peat has attracted considerable attention; this nitrogen is practically in an inert condition in the raw material, and in order to utilise peat successfully as a manure the nitrogen must be transformed into a more active compound such as a salt of ammonia.

The idea of subjecting peat to the water-gas process was suggested by Dr. L. Mond, and the first plant erected for the purpose was that at Orentano in the province of Lucca, Italy; it has since been much improved by the addition of plant for preparing and drying the peat. The next important works of the kind were those at Osnabruck (Hanover) under the direction of Drs. Frank and Caro, but owing to the difficulties connected with the preparation and drying of the peat, these works may be considered as being still in the experimental stage, as are other works started in England. The last works to be erected were those at Codigoro, Italy, where all difficulties have been successfully overcome. In fact the only two important undertakings for the utilisation of peat are those of Orentano and Codigoro belonging to the "Società per l' utilizzazione dei combustibili italiani."

The process adopted for treating peat is the following: The peat, properly dried and broken up, is thrown into a turret-shaped oven 26 ft. to 33 ft. high, called the gas oven, which is fed at intervals from the top. The peat burns only in the lower part of the turret, the combustion being regulated by a jet of hot air and steam. The water vapour decomposes on the incandescent mass, producing, together with the other combustion gases, the so-called water gas, or in this case Mond gas, which collects in the top of the oven. It is produced at the lowest possible temperature, and the nitrogen evolved from the peat combines with the nascent hydrogen and forms ammonia. The gas thus produced is then washed to free it from the tarry products it contains and led into a leaden chamber where it is met by a spray of sulphuric acid which converts the ammonia into sulphate, while the remaining gas is purified, cooled and burned under the steam boilers, in the drying ovens or in gas motors. In this way about three-

* Summary of a lecture by Professor Ugo Rossi given at a meeting of the Association of Italian Agriculturists. Reprinted from the "Monthly Bulletin of Agricultural Intelligence," Rome.

quarters of the quantity of nitrogen contained in the peat is converted into sulphate of ammonia. A peat containing 2·5 per cent. of nitrogen yields about 175 lbs. of sulphate of ammonia to the ton.

The first factory was erected at Orentano in 1907, but only began to work in 1910. At first the peat was dried in the open, but as this system proved quite unsatisfactory artificial drying was resorted to. Peat taken from the pit contains 50 per cent. by weight of water, and this quantity is now most successfully reduced to 25 per cent.

At present 1,800 cubic ft. of peat can be treated daily, yielding 50 tons of sulphate of ammonia per month, and before long the output will be doubled. The gas is used in the works and at a central station developing about 800 h.p.

The results obtained at Orentano encouraged the company to erect large works at Codigoro (Ferrara, Italy) in 1912; these are now capable of dealing with 150 tons of dried peat daily, and of turning out from 10 to 12 tons of sulphate of ammonia per day. The peat beds at Codigoro are upwards of 2,500 acres in extent. The company has already spent £240,000 on the two factories, but it can now produce sulphate of ammonia at 4*s.* 10*d.* to 5*s.* 7*d.* per cwt., while the market price is above 12*s.* per cwt.

FOREST FIRES IN THE SOUTH OF FRANCE.

Some idea of the immense damage caused by forest fires in the departments of the south-east of France is given in a report lately published by the *Syndicat forestier de Provence.* It appears that, notwithstanding the exceptionally dry summer in 1913, only two fires of importance occurred in two of the departments, namely, one at Quinson in the Basses Alpes, and the other in the neighbourhood of Auribeau in that of the Alpes Maritimes.

In the Department of the Bouches-du-Rhône, where the forests cover an area of 85,579 hectares (211,380 acres), of which 25,087 hectares (61,965 acres) are the property of the State, and 60,492 hectares (149,415 acres) belong to private owners, the damage done by fire was comparatively insignificant, being 230 hectares (568 acres), which was the result of eight outbreaks, one of which was attended by loss of life.

On the other hand, the Department of the Var seems to have suffered very severely, and of a total area of 260,000 hectares (622,200 acres, nearly 1,000 square miles) no fewer than 12,384 hectares (30,588 acres), or about 5 per cent., were destroyed by twenty-six fires which occurred between May and September.

Of these 12,384 hectares of forest, 11,040 hectares (27,268 acres) were burnt in six fires which occurred during the months of July and August. The two largest of these, viz., at Bormes and at Ollières, destroyed upwards of 3,000 hectares (nearly 7,500 acres) each.

The other twenty fires were from two hectares (five acres) to 350 hectares (864 acres) in extent, and no account is taken of many minor outbreaks when less than two acres of forest was destroyed.

The timber destroyed consisted chiefly of various species of oak, including a large proportion of cork trees, and covered an area of 7,495 hectares (18,512 acres); the remainder, 4,889 hectares (12,076 acres) in extent, were pines.

With regard to the causes of these fires, nineteen are attributed to negligence or imprudence, probably, in most cases, originated by lighting fires in or in the neighbourhood of woods or forests, four were attributed to malice, and three to negligence and malice combined. In six cases the assistance of the military was called into requisition to stop the progress of the flames, whilst in nineteen cases the fires were extinguished by the inhabitants in the neighbourhood, and in one case only did the fire burn itself out. In most cases aid arrived too late.

Many suggestions are made for the prevention of forest fires, or for arresting their progress when once alight. Unfortunately the heavy expenditure that would be incurred in many of these plans renders their application impracticable.

PHILIPPINE PROGRESS IN BASKET-MAKING.

The most notable feature of the basket-work exhibited at the last Philippine Exhibition was the note of uniformity of design throughout the whole. Every part of the archipelago was represented by practically the same type of baskets. This uniformity has resulted from a campaign carried on by the Bureau of Education, under whose supervision practically all the basket-making for the export trade is done. Another noteworthy feature was the large number of types of bamboo-nito and all-bamboo baskets, copied from indigenous types that have been standardised. Some of these are closely akin to Javanese and Bornean kinds. Considerable stress is laid on the symbolism of the native types, and the opinion, borne out by market experience, is that these indigenous types are more profitable than the evolved or copied types, such as the Polangui and coiled baskets.

Among the most popular types in the exhibit which are being made for the trade may be mentioned the following, says the American Consul at Manila: A miniature bamboo-nito rice-holding basket covered with a miniature winnowing basket of the same material made in Pangasinan—this is popular for a trinket basket; buyo boxes, after an old Iloilo pattern with zigzag decorations on the side and bottom; the nito basket, sewn through the strip of bamboo that forms the side, after an old Malayan form of decoration, the top decorated with black wood inlaid on white wood, representing two birds; the small Igorol camote basket; the harvest basket from Palawan; the fishing basket of the Ilocano, with superimposed blackened bamboo spokes; a very old type of holding

basket in a weave common to the Skanras of North Borneo, the Tirrurays of Mendanao, and the Japanese; the oblong buyo box of Iloilo; the ceremonial marriage basket of the Batangas Tagalogs; modifications of the Ilocano fishing basket in forms of waste-paper baskets, sewing baskets, and work-baskets; the rice harvesting basket of Cuyo, with typical Cuyo rim perforated and decorated with a nito binder; the Cuyo planting basket, used for holding the seed of upland rice; the seed basket of Calawit, Busuanga, the rim finished with a type of centipede weave in nito, a design exceptionally even and the weave fine; cigarette cases of blackened bamboo from Busuanga; buri boxes; buyo boxes of North Palawan, of fine work and interesting symbolism.

Baskets of the evolved types shown in the exhibit were: all-wool bamboo work-baskets from Pampanga; bamboo-nito handkerchief and collar boxes; winnowing baskets, mosaic design in coloured bamboo strips, the edge bound with nito, from Iloilo; handbag design, card trays, button boxes from Bulacan. The Polangui baskets of standard types and ornate designs show evidence of great popularity abroad. Unfortunately, the material from which they are constructed is difficult to secure in thickly populated districts where makers abound. The provinces where this material grows abundantly are sparsely populated. In view of this fact, it is probable that the supply of this class of basket for export will be limited. About Polangui, Albay, where this basket originated, already the supply of materials is diminishing. These baskets are becoming popular in the United States, and local agents are buying large supplies for well-known American firms. The provinces of Mendoro and Misamis are well supplied with the materials for this type of basket, but lack workers.

The coiled stem baskets consist of rattan, nito, and lukmoy. The rattans come from Nueva Vizcaya. The best nito work comes from Samar, where the coiled nito baskets are mostly produced. These materials are formed into desk trays, tie boxes, button boxes, jewel boxes, and round and rectangular trays. The coiled strip baskets exhibited were largely of new design and untried as to durability. There were shown a market basket of coiled karagumoy strips, with lukmoy and rattan body; a large tray of lupids on rattan made in Bohol; a striking black-and-white work-basket made in Albay; a jar-shaped one of bamboo coiled work made in Bulacan; a small tray of buri-leaf strips coiled on lukmoy, made in Mindoro; pin trays in lupis coiled on rattan, made in Samar. These coiled strip baskets present a very favourable appearance and are liked by connoisseurs, but they have not proved themselves on the market. The division of the exhibit devoted to the plaited buri and pandan baskets displayed some fine samples of karagumoy baskets from Albay Province, and some excellent buri baskets from Romblon and Capiz Provinces.

Pandan is a material widely distributed in the islands and easily obtainable, but the lasting qualities of the material have not been given a thorough test. The coiled fibre baskets of abaca (Manila hemp) and maguey coiled on rattan are giving great satisfaction. These baskets come principally from Southern Luzon and the Visayas, where abaca is chiefly grown, and the Ilocano Province, where maguey is extensively cultivated. In this kind of basket the design of the noted Philippine moth is seen to the best advantage. Many of these types nest or telescope well, and are suited to export. In durability they are probably unsurpassed, and they offer a wide range for new designs.

There remains to be noted the line of "air root" baskets or hand-bags, made chiefly in Tayabas from the material known locally as lukmoy, elsewhere as "air root." These hand-bags were designed to take the place of the Japanese article formerly so largely imported into the islands, and have to a great measure done so. The hand-bag is growing in local favour, and may well supersede the imported article and compete with it in outside markets eventually. The same material is made into other popular types, such as covered work-baskets, which of course are less convenient for export. In view of the great wealth of the material and the intelligence of native workers under proper training, the basket-making industry is going forward by leaps and bounds in the Philippines, and promises to become one of the leading industries when time and experience shall have more completely mastered the intricacies of providing for an export trade. The necessity of manufacturing for the foreign market has in recent years tended to eliminate many of the more flimsy classes of baskets, and to emphasise durability and shipping facility. For the export trade, types that nest or telescope readily are evolving, particularly in the larger makes.

THE PANAMA HAT.

It is believed that the first toquilla or Panama straw hat was made 285 years ago in the province of Manavi in Ecuador. In those days Panama was the chief distributing emporium for articles produced on the west coast of South America, so hats woven from the toquilla straw in Manavi, and exported from Panama, came to be called Panama hats, and the name has clung to the well-known fabric ever since. The plants which yield the toquilla straw are a species of stemless screw pines, the most important growing wild in the hot, moist regions of Ecuador and Colombia, and also along the head-waters of the Amazon. They attain a height of 6 feet to 10 feet, and present the appearance of diminutive fan-shaped palm trees. Many attempts have been made to cultivate the plants, but unsuccessfully, for it seems to be only in the wild state that the characteristic qualities are developed. The seeds are sown in furrows on low, wet land, during the rainy season, after which little attention is devoted to them. When about 5 feet high, the young leaves are cut before expanding, and are ready to be prepared for use.

After the removal of the veins, the leaves are dipped repeatedly in boiling water, and then exposed to the sun to be bleached. The straw is then carefully selected, its value depending upon the length, thickness, colour, and number of strands obtained from each leaf. The coarser straw is utilised in making small baskets, ornaments, bags, and other articles.

Thousands of the natives of both sexes and all ages throughout the interior of Ecuador are engaged in weaving hats, the work being carried on from a little after midnight to 7 a.m., while the air is moist, as the straw becomes brittle during the day.

The necessary qualities of a fine hat are durability, strength, elasticity, impermeability, and the ease with which it can be washed, if soiled. It may be rolled up without injury, and will last for many years, but a broken straw in the crown diminishes its value by one half. Three to six months, working four or five hours each day, are required to complete the best hats, but children will make two of the cheapest grade hats from undressed straw in a day.

The finest hats ever made, as it is said, were the work of a native Ecuadorian named Palma, which were purchased for $200, or £40 each, and presented to the Emperor Napoleon III. and Marshal MacMahon.

The only objection to the Manavi hats, so the *Bulletin of the Pan-American Union* says, is that they are all of identical shape, no attempt having been made to adapt the forms to modern tastes and ideas of fashion. A hint to be borne in mind is that injuries should be repaired at once, as otherwise the hat soon becomes valueless. When not in use the hat should be rolled up carefully and wrapped in camphored paper. During the year 1913 hats to the value of $1,127,508 were exported, principally to the United States, Germany, France, and Belgium. The toquilla straw hats are sold at prices varying from a few cents to $100 (= £20 sterling), or even more.

THE REVIVAL OF SILK CULTURE IN SPAIN.

The production of silk, which in the sixteenth, seventeenth, and eighteenth centuries formed probably the most important of Spain's industries, is being revived in Seville. Recent experiments, though limited, are encouraging. Four hundred years ago the silks of Seville, then the most famous in the world, were exported to all countries, for Spain was the first nation of Western Europe to take up silk culture. The industry was introduced under the Moors, and protected and encouraged by their Christian successors after the Spanish conquests. In 1519 there were in the city of Seville alone 16,000 silk looms. During that flourishing period the annual output of silk in the Province of Seville amounted to 880,000 lbs., and in the whole country to 27,000,000 lbs. The industry declined in the early nineteenth century owing to civil disturbances and heavy taxation, and especially to the prevalence among the silkworms of pebrine. By 1850 sericulture had entirely disappeared in the Seville district. The climate of Spain is excellent for this industry, and fine silkworms, such as were employed when silk cultivation was at its height, are available in the foothills of the Sierra Nevada, near Granada. The worm has a life of fifty days, during the first thirty of which, according to the American Consul in Seville, it grows to about 9,500 times its original weight. Ninety-six thousand small eggs of the silkworm weigh one ounce. The white mulberry tree, which grows in four years to such a size that its leaves may be utilised for feeding the silkworms, thrives in the Seville district. The tree reaches a height of 33 ft. to 49 ft., and a possible age of three hundred years. Moreover, as it puts forth new leaves after its first foliage has been gathered, it loses nothing in value as a shade tree; it is hardy in cold and drought. The Province of Seville has provided for the planting of white mulberry trees along several provincial highways. Permission has been given to persons without land to plant the trees along the now shadeless country roads, and railway companies have been requested to plant the trees along their lines. A manufacturer of silk thread in Seville has distributed gratis silkworm eggs of the first quality, and these may be purchased at cost price—about 9*s.* an ounce—from the principal promoting organisation at Murcia or Barcelona, or procured from the School of Sericulture recently established at San Juan de Aznalforache, two miles from Seville. The quantity of silk cocoons produced in Spain is estimated at 2,105,400 lbs. annually, valued at £182,000.

ARTS AND CRAFTS.

British Arts and Crafts at Paris.—The illustrated catalogue of the Exhibition of British Arts and Crafts held in Paris last year was sent round at Christmas time to the exhibitors, perhaps as a kind of gentle reminder that their possessions were still in safe keeping and that they might expect some day to have them returned to them. It is a fat quarto volume, profusely illustrated, is issued at the very reasonable price of four francs fifty centimes, and contains, besides the actual catalogue of objects exhibited, translations of short articles by well-known British craftworkers and experts treating of the various crafts. It is, therefore, a work of more than ephemeral interest. It was the custom at the earlier exhibitions of the Arts and Crafts Exhibition Society to include in the catalogue essays on different subjects connected with the exhibition, but these were naturally always written by members of the Society. The Committee for the British Exhibition in Paris was constituted on a wider basis, and the present catalogue reckons amongst its contributors not only the president of the committee (Sir Cecil

Smith) but also such well-known experts as Mr. William Burton and Mr. Alan Cole, who do not belong to the Arts and Crafts Exhibition Society. The result is that, though the greater number of the articles are written more or less from one point of view, the outlook displayed by the writers as a whole is a good deal wider than might have been expected, whilst Commendatore Walter Crane's introduction gives an admirable summary of the genesis of the Arts and Crafts movement in this country. The illustrations are, on the whole, very well produced, though in some cases a little more care would have resulted in the colour values being better preserved. The objects chosen for illustration cover a wide range. Morris tapestries, decorative paintings by Sir Edward Burne-Jones, cartoons and designs by William Morris, cartoons by Ford Maddox Brown, pottery by William de Morgan, a cretonne design by Lewis F. Day, and glass from the designs of Philip Webb, are included in the retrospective examples. The modern work embraces nearly all the artistic crafts; pottery is represented by the Pilkington Tile & Pottery Co., W. Howson Taylor, Mrs. Harold Stabler, Bernard Moore, the Martin brothers, and others; table glass by Messrs. James Powell & Sons; stained glass by R. Anning Bell, A.R.A., Harry Clarke, and others; embroidery by May Morris, and lace by the East Devon Lace Association, The Royal Irish Industries Association, and other societies as well as private workers. The illustrations of metalwork include, amongst other objects, Sir W. Goscombe John's Sceptre, a couple of maces by H. Wilson, Sir George Frampton's badge of office for the Master of the Art Workers' Guild, a two-handled vase by Omar Ramsden and Alwyn Carr, and a cup in silver and copper by J. Paul Cooper. The examples of book illustration are numerous and varied, whilst among the bindings the magnificent Dante, by Miss Adams, and the books of Douglas Cockerell deserve attention. There are some beautiful examples of letterpress from the Doves Press, and the work of Graily Hewitt, Edward Johnston, and Mrs. S. C. Cockerell shows what England can do in the way of lettering and illumination. Textiles, furniture, and wall-papers are but slightly represented.

On the whole, the catalogue is of extraordinary interest as showing at a glance better than any publication has hitherto done the results of the Arts and Crafts movement at their best. The works illustrated are representative, and they leave one with a feeling of pleased surprise at both their technical and their artistic qualities. They prove beyond a doubt that in some directions excellent work is being done. On the other hand, there is very little evidence that the movement at the present day (whatever may have been the case in the past) is doing much to help forward design for manufacture. William Morris, with all his energy and love of handwork, was happy to design wallpapers, cretonnes, and the like. The twentieth-century artist craftsman, apparently, can only be interested in work which he can execute entirely himself. Handicraft may be the gainer by this, but manufacture, and indirectly trade, are undoubtedly the losers.

Lettering, Illumination, and Printing.—It is at this season that there is always a good opportunity of judging how things are going with regard to lettering, illumination, and printing. Every year as the time draws near to Christmas, those of us who are interested in illumination and the like begin to scan the shop windows and the books of "private greeting cards" anxiously in order to see what the Christmas and New Year cards will be like. The tendency within recent years has been so much towards simple greetings, with perhaps illuminated initials or borders, that nowadays one has hardly to take account of purely picture cards. For some years past the general level of the better lettering and illumination has been slowly rising, though there has still been far too large a proportion of indifferent work, and the setting out of the "private greetings," always a difficult problem, has left a good deal to be desired. This year, however, the improvement in much of the lettering itself, as well as in its spacing and setting out, has been so marked that one has been forced to the conclusion that—patriotism apart—we are justified in thinking that the most unsatisfactory Christmas cards have been made in Germany. It is remarkable what a much smaller number of really tasteless cards seem to have been on the market this year than usual. That does not, of course, mean that all the cards or all the lettering on them has been good, but it does show real progress. Another very hopeful sign is the increasing variety of letter-forms used. Instead of confining themselves to one or two styles, scribes seem to be learning the wisdom of catholicity, and they are now much more willing than formerly to found themselves on any good model they come across, no matter in what century it may have had its origin.

The only unsatisfactory development which has to be noticed this year is in the direction of facsimile handwriting. If people want that kind of thing they must presumably have it; but would it not be possible for the manufacturers to draw the line somewhere, and not offer the public quite such bad examples of facsimile handwriting as some of them put upon the market?

When we turn to type and type-setting there are one or two points worth noting. The Christmas season, though it must have been a bad one for the book trade, brought its usual crop of publishers' announcements. These were in the main very satisfactory pieces of work, and the great majority of them were not only well planned but set out in good type. Further, the employment of old "printers' ornaments" by one or two firms helped to give their notices an air of distinction. Again, since the New Year, one of the best known London daily papers has changed the type of its headlines. The claim is that this has increased their legibility, and it is justified; but it has further, by substituting

a good square type for a thin one, very much improved the appearance of the pages. Little improvements of this kind are an indication of the increased care taken nowadays with regard to lettering, and of the greater estimation in which it is held. It is not so long ago that any sort of type was regarded as good enough for advertisements, newspapers, and the like.

Embroidery, Eastern and Western.—Within the last few years English needlewomen have shown a distinct tendency to turn their attention towards cross-stitch, tent-stitch, plait-stitch, and other types of embroidery which take their character in large measure from the square mesh of the material on which they are worked. This is a state of affairs which some embroideresses exult in and others condemn. It seems as though in truth it has both its bad and its good side. It inculcates habits of accuracy, but it also tends sometimes to encourage the love of a rather niggling style of work. Further, the most ardent advocate of the system of designing freely with the needle would hardly urge a Western workwoman to begin work which must of necessity be done by the thread without having carefully planned the main lines of her design, and needlewomen who do this kind of work commonly look about for a model to adapt or more often to copy. Unfortunately the examples most easily accessible to most people are just those least worth copying, and the result is that a good deal of the modern canvas-stitch work of all kinds is very dull and spiritless. The little collection of old embroideries from the Greek Islands and Turkey now on view at the Burlington Fine Arts Club ought to give such workers just the kind of direction they need. The designs on the whole are so vigorous and full of "go," the cross-stitch and other birds and beasts are so quaint and yet so alive, the conventional patterns so well balanced that the needlewoman who found no inspiration in them would be dull indeed. To the student concerned with the history of embroidery and the relation of the work produced in one country to that to be found in another, the exhibition has an added interest. It knocks yet another nail into the coffin of the old idea of "Crete embroidery," and it makes it apparent that there is a more direct connection than is sometimes allowed for between the work executed in the Greek Islands and that which comes from those parts of Italy which in old days were in close touch with the East.

CORRESPONDENCE.

THE INDIAN INDIGO INDUSTRY.

Chinese Alkaline Extraction Vat.

In continuation of my letter published in the last issue of the *Journal*, I should like to add a few remarks about this method of extraction, an account of which I read in a Bulletin issued and written by (if I remember rightly) the Superintendent of the Botanical Gardens, Singapore. It is now out of print, but as the Chinese method is the opposite of the Behar method an allusion to it may be of interest.

The author mentioned that the Chinese put lime along with the plant into their steeping vats, and, after extracting the dye, often replanted the steeped plants.

This indigo, I believe, is, or was, used locally by the Chinese in the Malay States, and exported to China, but never found its way to other markets. I think this alkaline method of extraction may be worthy of experiments.

It is interesting here to note that the alkaline vat is now used by our British and, I believe, German dyers in preference to the acid fermentation method of reducing indigo blue to indigo white, as the latter method was capricious and wasteful.

It seems to me that the alkaline method of extraction should be tried in Behar, using, perhaps, ammonia gas (more suitable than lime) to maintain the vat liquor throughout the steeping in a faintly alkaline, or perhaps simply neutral, condition, but here again we want the advice of the best British scientific brains.

Japanese Natural Indigo Industry.

There is, or was up to a few years ago, a small natural indigo industry in Japan, but I do not know what method of extraction they employed. I was informed that they made extensive trials of the natural dye and synthetic indigotin during their war with Russia, and that the results were in favour of the former.

With regard to Professor Henry E. Armstrong's most interesting article on "The Future of Indigo," which appeared in the *Journal* of the 8th inst., I should like to say simply that we planters trusted entirely to our late scientific advisers in India, and when they told us the margin for improvement was limited to 15 per cent. we accepted their statements in good faith, and came to the conclusion that there was no scope for further improvements in manufacture. I ask, in fairness to the planters, Are we to be blamed if we, after repeated losing seasons, decided to reduce or discontinue entirely our cultivation of indigo and efforts in further research work in this department of our industry?

LEWIS J. E. HAY,
Retired Behar Indigo Planter.

BRITAIN AND GERMANY IN RELATION TO THE CHEMICAL TRADE.

I have read Dr. Ormandy's paper on "Britain and Germany in Relation to the Chemical Trade" with a great deal of interest. I have been connected with the coal-tar industry for nearly fifty years, but no doubt we as manufacturers have allowed Germany to wrest from us much of the trade which we ought to have maintained. It has been due not to our own fault, but rather to

the fault of successive Governments, who have not only ignored us but have fostered German industries by buying from them to our detriment. In my own branch we have been undersold by German competitors simply because the German Government subsidised their own manufacturers, whilst no British Government has held out a helping hand to assist us. Our patent laws have been interpreted to our disadvantage. It is not the manufacturer who is to blame, but the Governments who have failed to help him.

R. LE NEVE FOSTER

OBITUARY.

SIR OWEN ROBERTS, M.A., D.C.L., LL.D.—By the death of Sir Owen Roberts, which occurred on the 6th inst. at his house, Henley Park, near Guildford, the Society has lost one of its staunchest supporters and one of its most valued members. Elected in 1879, he became one of the Society's Treasurers in 1880, and from that date to the present time he has served on the Council with one solitary interval of a year. On five occasions he filled the office of Treasurer, in each case for the full term of five years, except on the last occasion when his tenure of office was interrupted by his election as Chairman of the Council. This post he only held for a single year in consequence of his dislike to the delivery of a second address, a duty the nature of which was always irksome to him. In the intervals between his various treasurerships he served as one of the Vice-Presidents. Such a record of service, extending over an almost unbroken period of more than thirty-four years, is absolutely unique in the Society's history. The value of his services it is really difficult to overestimate. His influence secured a large amount of financial help from the City Companies and from individuals, while his able management of the Society's finances contributed largely to its present prosperity.

He was born in Carnarvon in 1835, and on leaving school he became a scholar of Jesus College, Oxford, of which college later in life he was made an Honorary Fellow. In 1865 he was called to the Bar, but he never practised, and for some time he held a clerkship in the War Office. This post he gave up in 1866 to become Assistant Clerk to the Clothworkers' Company, in preparation for his appointment as Clerk in the following year. Here he found the work of his life, for he held the office till 1907, when he was elected Warden on his resignation, and two years later he was paid the very considerable compliment of being elected Master of the Company in recognition of his services.

When he first took office the City Companies were not in high repute. They were wealthy, and had the credit of being wealthier, and they were accused of devoting their funds to their own purposes while neglecting the trades for whose benefit they had been founded. It was admitted that they were liberal and judicious administrators of large charitable funds, but there was a considerable popular demand for their wholesale abolition, and for the application to public purposes of their large resources. This is not the place to discuss the truth of the accusations or the justice of the demands. The matter is mentioned only because it was the life work of Owen Roberts to rescue the great City Companies from the contumely with which they were overlaid, and to secure the judicious administration of their surplus funds for purposes of education and scientific research. The whole credit must not be assigned to him—he had able and zealous coadjutors. It cannot be stated for certain that he was the first to conceive the idea of devoting City funds to technical education, but he surely was the first to realise the importance of the work, to perceive that there was a great public purpose to be effected, and that the salvation of the ancient City Companies lay in taking up the duty of effecting it. How the old Trade Guilds of the City of London could again assume the duties which for centuries they had allowed to lapse was a very difficult problem. It was solved by the decision that they should form an organisation to provide for what it was at the time believed to be the greatest industrial want in this country—the want of scientific training for its industrial workers. Hence was developed the scheme for the encouragement of technical education, of which Owen Roberts was the most earnest promoter and the most zealous advocate.

Among those who co-operated with Roberts may fairly be mentioned two other clerks of City Companies, Sir William Sawyer of the Drapers and Sir John Watney of the Mercers, with Sir Frederick Bramwell the Prime Warden of the Goldsmiths. These and many others worked earnestly on behalf of technical education, but it must always be remembered that the man who helped most to initiate the movement and who contributed the driving-power for its successful development was Owen Roberts. The history of the movement, which commenced in 1877 with the formation of a committee of representatives from twelve of the Livery Companies and resulted in the establishment of the City and Guilds Institute, cannot be recorded here; suffice it to say that Sir Owen Roberts devoted to its development and organisation the same constant and earnest care that he gave to its foundation, and that in the last years of his life, when he was an active member of its council, and the chairman of one of its most important committees, he was as keen a worker on its behalf as during the earlier years when he acted as one of its three honorary secretaries.

Nor were his exertions in promotion of technical education confined to London. At his instance the Clothworkers' Company evoted large sums of

money to the provision of textile industries and dyeing departments at the Yorkshire College, which eventually developed into the University of Leeds, and also liberally assisted other technical education institutions in various parts of the country. Nor was it merely that ample funds were provided for the foundation of lectures and the equipment of laboratories. Care was always taken that those funds were carefully utilised and judiciously applied. Roberts's shrewd business instincts and financial capacity ensured this, and he also possessed a singular capacity for estimating the value of other men's work, and getting the best results out of those with whom he co-operated. Consequently his advice was always sought and readily followed.

If, however, it was in connection with the industrial applications of education that he was best known to the public, he was perhaps really more attracted to the promotion of female education, and in this he took a keen personal interest. He was one of the promoters of Somerville College, Oxford, and always took a great interest in its welfare.

But educational matters alone by no means absorbed all his available energy. If he was not the first to suggest a practical scheme for the amalgamation and utilisation of the parochial charities of London, he certainly took an early and important part in the consolidation of the large funds belonging to the parishes and to various old Trusts in the City of London, which had certainly been to a very large extent wasted. The result was the formation in 1891 (under an Act of 1883) of a central governing body—the City of London Parochial Charities Trust—and into their hands was given the administration of these funds, amounting to a very large annual sum, over £100,000, which is now judiciously administered for various charitable and educational purposes. These purposes include the maintenance of City churches, the support of polytechnics and of technical education generally, the provision of open spaces, grants of pensions, and similar objects. Although at the time of its introduction the scheme met with a good deal of opposition from vested interests in the City, it has long since been admitted to be a useful and valuable reform. Sir Owen Roberts was the first vice-chairman of the Board of Governors, and the first chairman of its Estates Committee. Both of these offices he held until his death, and he exerted a potent influence over the work of the Trust.

In addition to all the work he did of a public nature, he found time to take part in the administration of various commercial companies. He was a director of several important insurance companies, of the Improved Industrial Dwellings Company (a semi-philanthropic institution which turned out a sound business undertaking), of the City of London Real Property Company, and of certain others.

The various bodies, educational and other, with which he was associated, and in the direction of which he took part, were very numerous. He took an active part in the reconstitution, under a scheme of the Charity Commissioners, of the old City Foundation established in 1710 by Sir John Cass, with its schools and technical institute, of which he became the Chairman. He was also for fifteen years chairman of the Central Foundation School associated with the name of the Rev. Prebendary Rogers, and for eleven years he acted on the Technical Education Board of the London County Council. He was also for some time chairman of the London Polytechnic Council. He served on the Commission for the reconstruction of the University of London on a teaching basis, and was for six years a member of the senate of that University. He was a member of the Council of King's College, of the Council for the Extension of University Training, and of the Governing Body of the Imperial College of Science and Technology. At the time of his death he was a member of the committee of the Athenæum Club, and for some years he was Treasurer of the Society of Antiquaries.

He was knighted in 1888. He was three times married. Lady Roberts, who survives him, is a daughter of the late Mr. John Chadwick, of Stockport. By his first wife he had one daughter, who is married to Dr. Robert Armstrong-Jones. By his second wife he had two daughters, the elder of whom is married to Mr. William H. Davison, the present Mayor of Kensington, and one of the Treasurers of the Society, while the younger, who died some years ago, was married to a son of the late Sir Ralph Knox, K.C.B.

He was one of his Majesty's Lieutenants for the City of London, and was a Deputy-Lieutenant for the County of London and the County of Carnarvon, of which he was High Sheriff in 1908. He was a Justice of the Peace for the counties of London, Surrey, and Carnarvon.

As may be judged from the above summary of his various interests, Owen Roberts was a man of the shrewdest judgment and singularly astute. His financial capacity was remarkable, and his intellect of the quickest. He made no pretence to scientific knowledge, or to literary power, but his opinions on political, social, scientific and literary matters, if quickly formed and promptly expressed, were sound and judicious, always moderate, never extreme, but uniformly sensible. Gifted with the warmest heart and the most affectionate nature, he had numerous friends who appreciated his many charming qualities and loved him for his genial disposition. It seemed to be ever a pleasure to him if he could do anything to promote a friend's welfare, or further his objects, and to this end he would spare no pains. Many went to him for counsel and advice, and he was ever ready with both. The busiest of men, he always had time to help those who wanted help, and he reaped his reward in the affectionate regard of the large circle of friends who now mourn his loss.

GENERAL NOTES.

New Route from Petrograd to London.—It is stated in the *Corriera della Sera*, of Milan, that a new route from Petrograd to England will shortly be available for traffic. From this it appears that the construction of a short line which will connect the railway system with that of Sweden is being pushed rapidly forward. This missing link, which is only 20 kilometres (12½ English miles) in length, will connect Tornea, the present terminus of the lines in Finland, at the northern extremity of the Gulf of Bothnia, with the Swedish network at Karunga. From this place passengers can reach Bergen (Norway) by rail, without change, and travel thence by sea to Aberdeen. It is expected that the journey from Petrograd to London will not occupy more than 5½ days.

Bank Dividends.—The directors of the London County and Westminster Bank, Limited, after making provision for bad and doubtful debts, and applying £336,000 in writing down investments, have declared a dividend of 10⅝ per cent. for the past half-year (less income tax), making a total distribution of 21¼ per cent. for the year 1914. The directors of the London City and Midland Bank, Limited, recommend a dividend for the last six months at the rate of 18 per cent. per annum, less income tax. The dividend for the year 1913 was at the same rate. The net profits of the Union of London and Smiths Bank, Limited, for the past half-year, after payment of all charges and making provision for all bad and doubtful debts, amount to £280,682, to which has to be added £232,372 brought forward, making a total of £513,055. The directors recommend a dividend at the rate of 10 per cent. per annum, subject to income tax. The directors of the London Joint Stock Bank, Limited, report that the net profits for the past year, including £62,326 brought forward, amount to £515,500. Of this sum £163,350 was absorbed by payment of the interim dividend in July last, and the balance they dispose of as follows: £100,000 as provision for any further depreciation in the value of securities; £163,350 in payment of a final dividend of 16*s*. 6*d*. per share, being at the rate of 11 per cent. per annum (less income tax) for the past half-year, the balance of £88,800 being carried forward. The directors of the London and South Western Bank, Limited, recommend a final dividend for the year at the rate of 16 per cent. per annum, less income tax, and that the balance of £72,291, compared with £57,600 in 1913, be carried forward. In July an interim dividend at the rate of 18 per cent. was paid, thus making a total dividend for the year of 17 per cent. The directors of Messrs. Barclay and Co. have declared out of the profits for the half-year ended December 31st, an interim dividend of 4*s*. per share, being at the rate of 10 per cent. per annum on the "A" shares; and 7*s*. per share, being at the rate of 17½ per cent. per annum on the "B" shares, subject in each case to deduction of income tax. The interim dividend will be payable on and after February 1st to those shareholders whose names were registered in the books of the company on the night of December 31st last. The directors of Lloyds Bank, Limited, have declared an interim dividend of 14*s*. 6*d*. per share, being at the rate of 18⅛ per cent. per annum. The directors of the Capital and Counties Bank, Ltd., have declared an interim dividend for the past six months at the rate of 14 per cent. per annum. The directors of Williams Deacon's Bank, Limited, have declared a dividend for the half-year ended December 31st last at the rate of 14 per cent. per annum, less income tax.

The Manufacture of Thymol.—The *Times* draws attention to the fact that hitherto the manufacture of the well-known antiseptic, thymol, has been practically confined to Germany, notwithstanding the fact that ajowan seeds, the oil from which is almost the sole source of commercial thymol, are grown on a large scale only in India. No further supplies of thymol being forthcoming from Germany, owing to the war, the price had increased almost eightfold by September last, and is even now 21*s*. 6*d*. per lb. as against 5*s*. per lb. before the war. There is no reason why the United Kingdom should not become the chief centre for the manufacture of thymol. The manufacturing process is quite simple, and ample supplies of ajowan seed are available in India. The Imperial Institute, which has devoted attention to this subject, has made inquiries in India, and is prepared to put intending British manufacturers of thymol in touch with Indian exporters of the seed. Fortunately, too, a British Possession can provide a substitute for thymol if such be required. This substance is carvacrol, which is obtained from oils derived from a variety of plants, but particularly from the origanum of Cyprus. At the instance of the Imperial Institute this Cyprus origanum oil is already being produced in commercial quantities from wild plants in Cyprus, and in 1913 was exported thence to the United Kingdom to the value of £980. It is believed that the plant can be cultivated profitably and on a large scale in Cyprus, and experiments in this direction are understood to have been begun.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 20.—J. A. Hunter, "The Textile Industries of Great Britain and of Germany." Lord Rotherham, President of the Textile Institute, will preside.

January 27.—Hon. John Collier, R.O.I., "Portrait Painting." Lord Sanderson, G.C.B., K.C.M.G., will preside.

February 3. — Octavius Charles Beale, Chairman of the Australian Manufacturers'

Association, "Imperial Industrial Development after the War." George R. Parkin, C.M.G., LL.D., D.C.L., Organising Secretary of the Rhodes Scholarship Trust, will preside.

February 10.—F. Vincent Brooks, "British Lithography in 1915."

February 17.—Arthur Wilcock, "Decorative Textiles, and the Designer's Relation to the Industry."

February 24.—W. J. Ashley, M.A., M.Com., Ph.D., Professor of Commerce in the University of Birmingham, "The Economics of the War."

March 3.—William Poel, "Shakespeare's Profession."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 21.—Henry John Elwes, F.R.S., "Nepal." The Right Hon. Sir Herbert Maxwell, Bt., F.R.S., will preside.

February 11.—Captain Sir George Duff Dunbar, Bt., I.A., "Tribes of the Brahmaputra Valley." Lieut.-Colonel Sir Francis Younghusband, K.C.I.E., LL.D., D.Sc., will preside.

March 18.—Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army."

April 15.—M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 26.—Major E. H. M. Leggett, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda."

February 2.—Edward R. Davson, "Sugar and the War."

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced:—

Thomas Worthington, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. Thorne Baker, "The Industrial Uses of Radium."

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

J. W. Gordon, "Patent Law Reform and the War."

E. W. Hulme, "Patent Law."

H. M. Thornton, "The Industrial Uses of Coal Gas."

D. Y. Cameron, A.R.A., R.E., "Etching."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

A. S. E. Ackermann, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

Lady Lugard, "The Work of the War Refugees' Committee."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

May 13.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March 2, 30.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

F. Mollwo Perkin, Ph.D., F.I.C., F.C.S., M.Inst.P.Tech., "Oils, their Production and Manufacture." Three Lectures.

Syllabus.

Lecture I.—January 18.—Mineral oils—Historical — Their sources — Oil-fields and their distribution — The production and refining of natural mineral oils—The shale-oil industry and its possibilities.

Lecture II. — January 25. — Low temperature carbonisation—cracking of oils—Motor spirit—Fuel oils.

Lecture III.—February 1.—Vegetable oils—Raw materials—Sources of supply—Methods of manufacture—Methods of refining—Edible oils—Paint oils.

M. H. Baillie Scott, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Fothergill Lectures.

Monday evenings, at 8 o'clock:—

Professor Vivian B. Lewes, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

February 15, 22, March 1.

MEETINGS FOR THE ENSUING WEEK.

Monday, January 18...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. F. Mollwo Perkin, "Oils, their Production and Manufacture." (Lecture I.)

Victoria Institute, 1, Central Building, Westminster, S.W., 4.30 p.m. Rev. Canon E. M'Clure, "Modernism and Traditional Christianity."

Electrical Engineers, Institution of (Local Section), Mining Institute, Newcastle, 7.30 p.m. Mr. E. B. Wedmore, "Automatic Protective Switchgear for Alternating-current Systems."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. E. A. Molony, "Wells for Irrigation in India."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. F. C. Eden, "Ecclesiastical Buildings of Northern Italy."

Engineers, Cleveland Institution of, Corporation-road, Middlesbrough, 7.30 p.m. Mr. V. Stobie, "The Manufacture of Electric Steels in the Stobie Furnace."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. R. H. Vigor, "Scaffolding."

TUESDAY, JANUARY 19..Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Professor S. J. Chapman and Mr. D. Kemp, "The War and the Textile Industries."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Discussion on Some Points in connection with the Scientific Development and Practical Applications of Searchlights.

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Muscle in the Service of Nerves." (Lecture I.)

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. R. A. Mallby, "The Production of Lantern-slides of Great Transparency, and the Tinting of them with Colours also Transparent."

Engineers and Shipbuilders in Scotland, Institution of, 39, Elmbank crescent, Glasgow, 8 p.m.

WEDNESDAY, JANUARY 20..ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. A. Hunter, "The Textile Industries of Great Britain and of Germany."

Meteorological Society, at the Surveyors' Institution, Great George-street, S.W., 7.30 p.m. 1. Annual General Meeting. 2. Account of the Proposed Climatological Atlas of the British Isles."

Optical Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. The Thomas Young Oration will be delivered by Sir James Crichton-Browne.

Entomological Society, 11, Chandos-street, W., 8 p.m. Annual Meeting.

Microscopical Society, 20, Hanover-square, W., 8 p.m. Dr. C. Singer, "Notes on the History of the Microscope."

THURSDAY, JANUARY 21 ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. H. J. Elwes, "Nepal."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. E. H. C. Craig, "The Prospective Oilfields of Western Canada."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Miss Ruth C. Bamber, "Report on the Fishes collected by Mr. Cyril Crossland in the Sudan." 2. Professor W. J. Dakin, "Narrative of his recent visit to the Houtman Abrolhos Archipelago, West Australia."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. E. S. Andrews, "Some Modern Methods of Arch Calculation."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 8 p.m.

FRIDAY, JANUARY 22...Chadwick Public Lecture, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Dr. F. M. Sandwith, "War and Disease." (Lecture II.)

Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir James Dewar, "Problems of Hydrogen and the Rare Gases."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Dr. A. Russell, "Practical Harmonic Analysis." 2. Mr. T. Smith, "Measuring the Focal Length of a Photographic Lens."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 8 p.m. Mr. J. Dewrance, "Standardisation of Pipe Flanges and Flanged Fittings."

SATURDAY, JANUARY 23...Royal Institution, Albemarle-street, W., 3 p.m. Dr. R. T. Glazebrook, "Aerial Navigation—Scientific Principles." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,244. VOL. LXIII.

FRIDAY, JANUARY 22, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 25th, 8 p.m. (Cantor Lecture.) F. MOLLWO PERKIN, Ph.D., F.I.C., F.C.S., M.Inst.P.Tech., "Oils, their Production and Manufacture." (Lecture II.)

TUESDAY, JANUARY 26th, 4.30 p.m. (Colonial Section.) MAJOR E. H. M. LEGGETT, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda." SIR OWEN PHILIPPS, K.C.M.G., will preside.

WEDNESDAY, JANUARY 27th, 8 p.m. (Ordinary Meeting.) HON. JOHN COLLIER, R.O.I., "Portrait Painting—the Technique of the Great Masters" LORD SANDERSON, G.C.B., K.C.M.G., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, January 21st; The RIGHT HON. SIR HERBERT MAXWELL, Bt., F.R.S., in the chair. A paper on "Nepal" was read by MR. HENRY JOHN ELWES, F.R.S.

The paper and discussion will be published in a subsequent number of the *Journal*.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SIXTH ORDINARY MEETING.

Wednesday, January 20th, 1915; LORD ROTHERHAM, late President of the Textile Institute, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bailey, Hollis Russell, 19, Congress-street, Boston, Massachusetts, U.S.A.

Barnard, George E., Park Estate, St. Lucia, British West Indies.

Brandt, Richard Frederick William, B.A., 5, The Boltons Studios, Fulham-road, S.W.

Cherry, Albert, Venezuela Central Railway, Caracas, Venezuela, S. America.

Cottingham, Walter H., Woolley Hall, Maidenhead, Berks; and The Sherwin-Williams Company, Cleveland, Ohio, U.S.A.

Duke, Sir (Frederick) William, K.C.I.E., C.S.I., 11, North-street, Westminster, S.W.

Harris, William A., A.M.I.Mech.E., St. Lucia Usines and Estates Company, Ltd., Castries, St. Lucia, British West Indies.

Heynes, James Baylis, British Vice-Consul, Messina, Sicily.

Hume, F. Charles, Jun., First National Bank Buildings, Houston, Texas, U.S.A.

Lloyd, Professor John Uri, Phar.M.Ph.D., LL.D., 3901, Clifton-avenue, Cincinnati, Ohio, U.S.A.

Lovett, Major-General Beresford, C.B., C.S.I., 59, Madeley-road, Ealing, W.

Morgan, Edward D., 170, Summer-street, Boston, Massachusetts, U.S.A.

Perkin, Dr. F. Mollwo, F.I.C., F.C.S., 199, Piccadilly, W.

Powell, Christopher Charles, 52, Langdon Park-road, Highgate, N.

Power, John Joseph, K.C., M.A., LL.M., D.C.L., P.O. Box 532, Halifax, Nova Scotia, Canada.

Shaw, George L., Antung, Manchuria, China.

Watson, F. Mackman, "Selwood," Rotherham.

Wood, George, 626, Chestnut-street, Philadelphia, U.S.A.

The following candidate was balloted for and duly elected a Fellow of the Society:—

Meriwether, Hunter M., 3616, Gladstone Boulevard, Kansas City, Missouri, U.S.A.

The paper read was—

THE TEXTILE INDUSTRIES OF GREAT BRITAIN AND OF GERMANY.

By J. A. Hunter.

It seems desirable at the outset to disclaim any kind of title to speak with the voice of final authority upon the thousands of nice points which are, in the last resort, involved in a comparison of British with German textile industry. Those matters far transcend any individual experience, for what we speak of comprehensively as textile industry is not actually a single thing, but a congeries of industries differing in themselves and between themselves. Remarkable differences of method, material and machines occur within single branches of the industry within our own country, and many more when a second country is brought into review. It will be possible only to deal with the broader aspects, tracing similarities where they occur and pointing out some salient dissimilarities. In proceeding to that task and illustrating the matter here and there with specific examples, I should like it to be understood that, *mutatis mutandis*, the illustrations given would apply to some other cases than those expressly named. In this country, as one need not say, there are divisions within the industry corresponding with the materials worked—cotton, wool, silk, linen and jute; divisions also corresponding with the class of work done—spinning, weaving and finishing. Structurally, the industry is much the same in Germany as in this country. Concerns are organised to do nothing but spin, or nothing but weave, in both countries, and in both alike sub-division is carried further in some directions than in others, leaving mills in special branches of business fully self-contained. In those respects there are no highly significant differences, the one fact claiming passing attention being that there remains in some parts of Germany a cottage-weaving industry of which we have no exact counterpart. In addition to the fairly numerous hand-loom workers engaged upon costly silks, there were recently some 7,000 hand-looms in Upper Franconia, Bavaria, weaving cheap and coarse mixed woollens for export. Such a survival is only possible where low wages are the rule. In the silk trade hand-looms are more numerous than in this country, but then the whole German silk industry is on a larger scale. In both countries hand-looms are a diminishing quantity in the silk trade, and are being replaced by power-looms electrically driven. In the German silk trade the standard of efficiency is admittedly high, and it is the habit of some British silk manufacturers owning modern factories to compare their own practice with German practice, which they accept as the standard.

Our textile industries are distributed more or less over the whole country with strong concentration upon certain centres, and with less important seats between; and Germany, with its Rhineland, Saxon and Silesian strongholds, and its sprinkling of minor centres, does not conspicuously differ. The geographical distribution is like the English in that the bunching is most marked in the neighbourhood of coal-fields.

In both, textile industry employs—or did in 1907 employ—substantially the same number of persons, approximately 1,100,000 in Germany and 1,200,000 in this country. This is not, however, to say that the industries are of the same size. The German census of production points to a gross output of £150 millions, where ours tells of an output at least twice as large. The discrepancy is striking, in view of the substantial equality in personnel, but no deductions can be drawn from the bare fact without regard to the composition of the industries.

In their degree all measures of the relative importance of industries in separate countries are defective. The quantity of material consumed, or of goods produced, or the respective capacities of the productive plants, all afford opportunities for error, and make it preferable to consider one point with another in drawing any comparison. The course is not invariably pursued in arguing to support a case, but for the general purposes of illustration it will be preferable to deal with both *pros* and *cons*. There are in the world, according to the International Federation of Cotton Spinners, some 145 million spindles spinning cotton. They are not all moving at the same speed or making yarns of the same fineness, but their number is known with approximate accuracy, so that they afford a limited index to the size of the industry. Of

these spindles some 56 millions are in England and $11\frac{1}{2}$ millions in Germany. Ranking next after the United States with its $31\frac{1}{2}$ millions, Germany occupied the third place in cotton spindleage. England has roughly five times as many spindles as Germany, but the spindles are not alike. The mule, or intermittent spinning machine, is the staple producer in England. The ring frame, or continuous machine, accounts for about half the spindles in Germany. With ring frames, which in this country are used principally for spinning warp, and in Germany are largely used for spinning Indian cotton and waste cotton, the two countries are about equally equipped, with some 4 to 5 million spindles each. Of mule spindles we have approximately ten to the German one, and it is apparent that in England cotton yarn is spun to a much higher average fineness. Per thousand spindles, according to the latest trade figures, British mills consume in a year 77 bales of raw cotton, German mills use 158 bales, or roughly twice as much, indicating that their yarns are more than twice as coarse upon the average. The difference, although considerable, is less violent than between the small Swiss industry, with its consumption of only $70\frac{1}{2}$ bales per 1,000 spindles per annum, and the rudimentary Japanese with its 690 bales. When in 1907 Germany had an outturn of cotton yarn valued at £$31\frac{1}{2}$ millions, our production was returned at £79 millions, or $2\frac{1}{2}$ times as much. With five times as many spindles and three times as many looms as the German, the British cotton industry must be called very much the larger in every respect.

There is a much closer correspondence between the sizes of the respective woollen and worsted industries. Not all the products of the woollen and worsted trades are manufactured into fabrics in this country, and accordingly the comparison cannot be limited to them alone. But when this is done the available data show for the United Kingdom, in 1907, an output of £42·3 millions in fabrics and for Germany £38 millions. The estimates of the total make, based upon the 1907 census, show that England combed nearly twice as much wool as Germany and spun about 20 per cent. more yarn. It is apparent also that England wove some 50 per cent. more length of cloth, 397 million yards against 270. Thus, although the English woollen and worsted industry is materially the larger, there is no such preponderance as in cotton.

The comparison is all in German favour when we come to silk. Where silk employs 32,000 in England, it employs 66,000 in Germany. Five millions sterling covers the gross output of English silk spinning and weaving, while the German industry has an output three times larger (or £14·8 millions) in silk tissues alone, apart from its output of thrown or spun yarn.

The German linen industry, once important, has now some 280,000 spindles, or fewer than half as many as the North of Ireland. It produced 69·9 million lbs. of yarn in the same year as the United Kingdom spun 158 millions.

The German jute industry has expanded of late years to dimensions which have given rise to complaints of over-production. It is, of course, wholly dependent upon Bengal for supplies of raw material, and in the open market it does not compete profitably with Calcutta and Dundee. The German output of jute yarn in 1907 of some 297 million lbs. was nearly three-fourths of the British 417 millions.

Thus in scale Germany has the advantage of us in the silk trade alone; a trade which in our country has for better or worse been exchanged for cotton and wool.

A broad resemblance may be traced in the fact that both England and Germany export something like half their total make; the Germans less than half, and the English more. The gross value of exported British textile manufactures was £176·6 millions in 1912 against the German £72·75 millions. Our export of cotton was £122 millions, theirs was £25·4; our export of wool goods £37·7, theirs £20·6; our export of silks £2·2 against their £11·9. In other words, our immense lead of £100 millions and odd arises in chief from the cotton trade, which has, of course, been built for export purposes, and exports some two-thirds of its production.

Some apology is required for so many figures, but without a few of them the general situation cannot be outlined. The trade of the two countries has not been all in finished goods, nor in the direct sense competitive, and it has been in an important part reciprocal. We have been in the way of sending textile manufactures and apparel to the value of some £$19\frac{1}{2}$ millions to Germany, and of buying £$14\frac{1}{2}$ in return. The two markets have depended on, or made use of, each other, and the industries have been interdependent too. We have been in the habit of supplying German industry with raw material; witness the 8 million lbs. of British wool shipped to that country last year, a quantity independent of the almost twelve times greater volume of colonial wool bought from the London Docks for German consumption.

German industry again has taken off our hands raw by-products generated in course of manufacture in this country. In preparing cotton we accumulate heavy quantities of cotton waste, and the soft or untwisted waste of Lancashire mills has gone extensively to Germany to be treated according to German systems, and to be worked up into soft yarn for machine knitting or weft for cheap flannelettes. When re-manufactured with or without an admixture of Indian cotton, such as Lancashire prefers not to use, some of this waste in the form of yarns and goods comes back to this country. Then in combing wool we remove short fibre, or noil, a by-product not suitable for the uses of worsted manufacturers, but valuable for blankets, tweeds, and various woollen cloths. Germany has been the chief destination for such wool wastes as are not used at home.

The German market, in a word, has been of service in taking these quasi-raw and surplus materials off the hands of the producers, and in realising a better price for them than might else have been obtained. The main operations are not, of course, carried on for the purpose of generating by-products. Wool is combed with the primary object of isolating the long fibre or tops, and of the wool-combing done in this country apparently seven-eighths is for the service of English spinners and the remainder for the use of spinners abroad. We export wool tops, and about one-third of the export quantity has gone latterly to Germany. A more important trade is that in the yarns into which combed wool is spun. Some 45 to 50 million lbs. of worsted yarn, meaning at least one-fourth of all the worsted spun in England has gone normally to Germany, there to be made into cloth, braid, carpets, hosiery, or what not. In worsted yarn of one class the German market has for many years been self-sufficing, spinning substantially all its own merino or botany wool, but relying chiefly upon Bradford for yarns made from cross-bred and British wools, Alpaca and mohair.

If it should appear strange that Germany, with all her industrial energy and ambition, has continued to resort to Yorkshire for nearly one million lbs. a week of certain kinds of worsted yarn, it can be pointed out that the instance does not stand by itself. There are other commodities for which Germany has always come to England, and some for which England has had to send to Germany. As is perhaps usually the case, the explanation of the matter is to be found, not in any single commanding reason, but rather in a complex of reasons. Bradford energies have accepted and followed a particular line, dispensing with everything not found to be indispensable, cutting down every expense to the minimum, and seeking incessantly new ways of making ends meet under the stress of competition. The art of blending long wools together to obtain the desired result at the lowest cost has been mastered thoroughly. The machines to comb the wool and spin the yarn are made upon the spot. The use of the machines can be had upon the most advantageous terms, as the outcome of the division of the trade into separate branches, and the existence of commission combers and spinners. All the apparatus is at hand for dealing with practically unlimited quantities of the given sorts of wool. And so far as investigators have been able to make out, the whole secret of success in this particular direction lies in the pure directness and simplicity of the methods employed. The product has been so necessary hitherto to German weaving manufacturers that a specially low import tariff has applied to yarns of this character, and German orders have provided the whole work of a large number of Yorkshire spinning mills. It may be worth observing that the German worsted industry has fared best with fine wools most nearly resembling those of Saxon and Silesian growth, and that the largest development in this country has been in wools most like those of English growth. "As the twig is bent, the tree is inclined," and it may be that the presence of native supplies of wool of a particular sort gave the respective industries their direction in the first instance.

German worsted spinners—and one might add French and Belgian as well—employ machinery for spinning the finer wools different from that employed in England. They use the intermittent machine or mule where we use the continuous spinning frame. This difference of practice results in a certain dissimilarity of the product. The mule permits a serviceable yarn to be made with less twisting of the fibres than is involved in preparing material for the frame, and thus gives a bulkier and more spongy thread invaluable in producing fabrics of certain types. It allows fibre of a given length of staple to be spun to rather higher numbers than upon the frame, and, by employing suitable wool combs, it is practicable to work without oiling the fibre, a dispensation which has sometimes been said to facilitate the dyeing of fabrics to fine shades, and which spares hosiery manufacturers some trouble in scouring knitted underclothing before sale. Mule-spun worsted

is probably never so durable in wear as the English cap-spun yarn; in some circumstances it is not so easy to weave, and for certain fabrics it is definitely less suitable even in appearance. Within limits the two kinds are interchangeable, but beyond those limits the one does not serve for the other. Often as he has been urged to take up the mule, the English worsted spinner has in general stood by his frames, and the decision may be said to have been dictated by results. Owners of machines of both types have found in their experience the frame to be the more consistently remunerative of the two. And although the last few years have seen a very considerable expansion of plants for spinning fine wools in England, the new machines have been almost exclusively frames. In effect, the available volume of business has been partitioned out, not by any formal or informal agreement between the parties, but by the logic of self-interest. The English have left the mule-spinning of fine wools to the Continentals, and they in return have left the production of frame-spun botany or merino to us. It remains open for anybody to depart from that practice at any time, and there is more present temptation to embark upon mule spinning in England than ever.

There may appear something paradoxical in the facts that while we have supplied Germany with its coarser worsted yarns, we have furnished that country with its finer cotton ones. While we have made the spinning frame our chief producer of worsted, the mule is enormously our chief machine for cotton. As between the two industries—worsted and cotton—and as between the two countries—England and Germany—the positions are almost exactly reversed. Cotton being native to neither, no question of the character of native supplies enters into the case, but some historical reflections may be apposite. Comparatively, the German cotton industry is a young one. Until Alsace was arbitrarily included within the Empire in 1871, cotton spinning was a minnow among industries, engaging only 1½ million spindles. It is still true to say that all the cotton spindles of Germany, with all those of France added to them, are fewer than those of the single town of Oldham. In a general way it is every spinner's desire to turn off yarn in coarse numbers, and the coarser the better, for thereby one gets off the greater weight. Ordinarily, the profit of the transaction is not made in the mechanical operation of spinning, prices for which in England are usually cut to a fine point by the excess of supply over demand, but upon the turn of the market—the buying and selling of the material used. There are always processes at work to prevent the coarse spinner from making all the money, but it remains desirable in all cases to get as large a turn-off as one can. In all the young manufacturing countries a beginning is made with the coarse numbers, and only as this line becomes relatively unprofitable are producers driven towards finer yarns, of which the production is necessarily slower and in which the requirements are more exacting. Fortunately for us, Lancashire possesses climatic advantages favourable to the production of the finest and most perfect yarns. And the million lbs. a week of cotton yarn, representing an annual value of £5 millions sent to Germany, consists largely of yarns finer than those that the Germans have found it advantageous to produce for themselves.

Finally, we have sold to Germany piece goods, not in such quantities as before 1879, when Bismarck launched his protective tariff, but to still considerable amounts. Of 76 million yards of cotton piece goods sent in 1913, approximately one-half were grey or undyed goods, on which the tariff is lighter than on coloured cottons. Some of them went for further manufacture—to be bleached, dyed, or printed, or to be embroidered by machine, and in part to be re-exported in this finished state. Facilities for obtaining temporary admission duty free have existed for the benefit of the German finishing industries and, in conjunction with the differential tariff favouring undyed goods, these have been of some appreciable use to them. However, as a customer merely for 2 per cent. of the cotton cloth exported, the importance of the German market does not rank high in the woven cotton trade.

Owing to the difference of scale a business worth a couple of millions per annum means more to British woollen and worsted manufacturers than to the cotton trade. The amount is, roughly, one-tenth by value of the exports of woollen and worsted cloth, and the German purchases have been preponderantly in goods of the highest class with an average value between 5*s.* and 5*s.* 6*d.* a yard. The market has been of especial moment, not to makers of cheap goods, but to firms whose claims to attention are built rather upon supreme excellence than upon advantages of price. Scotch tweeds, Huddersfield fancy worsteds and West of England cloths, corresponding in quality with those chosen by the best English tailors and resembling them

somewhat in design, have been sent for wear in Berlin and the great cities. The similarity in design is not complete, for every country has its own quirks and twists of taste, and our designers, playing up to Continental preferences, have supplied sporting novelties in colours and patterns in which one would not choose deliberately to be seen at home. They are goods in which our manufacturers have established what is called an individual ascendancy; an ascendancy moral in respect of taste and propriety, material in respect of finish and workmanship, and admitted in both respects. The cloths are not all of a fancy character, but flattery in its sincerest form has been applied with some pertinacity to English designs. German, and still more Austrian, firms have been in the way of copying the patterns produced at heavy expense by Scotch and Huddersfield houses, and drastic co-operative measures have been required to suppress the piracy. Protests in Berlin against the passion for English cloth, and petitions from German makers of cheviots praying for Imperial intervention to discountenance the wearing of English clothes, have further attested the position held by these goods in the German market.

It is, of course, inevitable that all trade to Germany in articles having the character of luxury should suffer from the war. The impoverishment of the classes accustomed to choose expensive clothes, the destruction of so large a part of the flower of German aristocracy, and the antipathy towards England and things English, all forbid the expectation of a return, in any circumstances, to the *status in quo*. The larger part of our trade with Germany, being that in semi-manufactures, is destined to suffer in at least the same proportion as the consuming industries. To what extent German textile industries may suffer is uncertain, but the war may conceivably give them a considerable setback, with effects perceptible in years to come. It can cause no surprise to hear mutterings of severer losses to be inflicted upon the British. One of the journals of the German textile trade was declaring a little while ago that the freeing of German industry from all dependence upon England, whether for goods or raw materials, would be the task immediately confronting the country after the war. No doubt efforts to that end will gain a new impetus, but it can, of course, be reflected that such efforts are not novel. Germany has done her best to dispense with English assistance in the past, and it is by no means certain that she will fare any better in the future. It is true that our sendings to Germany have been larger than German sendings to us, but it does not therefore follow that their market is of more importance to us than ours is to them.

It is at least arguable that the main part of the German supplies to the English market are actually the more readily replaced of the two; and that such of them as cannot economically be manufactured in this country can more easily be obtained from alternative sources than can the goods supplied to Germany by us. If, for want of suitable machines, we cannot produce the relatively small quantity of woollen and worsted yarn imported from Germany, there are machines quite equal to the task in France and Belgium. The inability is not admitted, because there are more ways than one in which the supply can be replaced by home industry, but there is this alternative in reserve. The case is similar also in respect of the imported woollen and worsted cloths and dress goods, valued at nearly £1½ millions per annum, which are also of the type made in the countries bordering upon Germany. We can perhaps count on the French for any requisite assistance also in making the home market independent of Germany for silks. Threats of making German industry independent of England in raw materials need dismay us even less. Dependent utterly upon Bengal for raw jute, mainly upon Australia and South Africa for wool, partly upon Bombay and Egypt for cotton, the Germans are in no position to proclaim a boycott, and the menaces issued in moments of exasperation can readily be given their proper value. The imported German goods of most importance to them and to us are German specialities, even as our exports are mainly in British specialities. Of some £7 millions worth of various manufactures of cotton imported from Germany something more than one-fourth is classified officially as piece goods, a heading which conceals the softer, cheaper and more dangerous classes of flannelette, calico printed in German designs, cotton tapestries and some other goods. The greater part of the cotton manufactures has consisted, however, of cotton hosiery and gloves, lace, trimmings and small wares. In part by the force of cheap labour, and still more by ceaseless application for one hundred years, Chemnitz has built up a trading position in the cheaper forms of knitted cottons as solid as any that has been built up in like circumstances in our own country. Again, by the aid of cheap labour and the development of special machines, the

Plauen lace-makers have evolved a German Nottingham which rests unbeaten in its own fields. In these and some other lines an effective monopoly has been erected; others hesitating to engage in bu iness promising little profit to any but the best-placed producers, and preferring to follow and develop some line of their own.

Obviously, this specialisation which has proceeded in both countries, and has differentiated the character of the industries carried on, has its bearing upon what is loosely called the capture of German trade. It is safe to assert that nobody wants business because it is or was German, but only because it is desirable in itself. The fact that the business was German is no evidence of its intrinsic desirability, and is rather even the reverse, implying some probability that the trade is not such as we are best equipped to transact. The capture of trade is spoken of frequently with a glibness which does no justice to the real intricacies of the case. and the person who is aware simply that English and German goods are somehow "made differently" is quite commonly without an adequate sense of what is implied in the act of making. The differences include the class of raw material employed, and it is observable that German and English manufacturers have not been in the way of selecting identically the same qualities of cotton, wool, silk or jute for their several purposes. The choice of material is conditioned by the types of machinery possessed, some being made for fibres of one quality, some for another. In turn the arrangements as to payment made with workpeople hinge jointly upon the class of material and of machine, and it can be said that some of the wage scales in force in England have taken fifty years to construct, and involve a more or less serious strike at every readjustment. Then in a complete factory all the parts are symmetrical and made to fit in with and feed each other, so that in introducing work of a new kind one is possibly disgearing one or two departments in order to accommodate another—granted that the work is of an order which can be done without acquiring new machines. If new machines are needed, the question of their accommodation arises, and for some of the machines requisite to perform German work in the German manner, manufacturers would need to build new mills. Given new and expensive mills, there remains the question first of finding workpeople, and next of training them to unaccustomed tasks. It will not be professed that all these difficulties affect every case, but such are the order of the troubles besetting those who are lightly advised to go about their work in a new manner and are sometimes reproached for not doing so instantly.

In this, as in most matters, there is room for the play of a healthy conservatism. Experience shows certain classes of business to be more desirable than others, and to be, for example, more stable. A manufacturer knows the vicissitudes of his adopted line pretty well; he has the measure of his competitors fairly exactly, and can calculate with some safety from experience. In entering a new field, normally occupied in force by competitors whose position and tactics are little known to him, unknown risks are opened up, and any person of good sense steps into it with some caution. A radical departure is not in practice made until every means has been exhausted to make the existing machinery, assisted perhaps by some auxiliary machines, do the work. Efforts thus far made to lay hold of German trade are not known to have led to heroic measures. The methods have been those rather of adaptation and modification. with a view to producing something so near to the German sample that it can effectively take its place. The process has not been continued long enough to bear all the fruits of which it is capable. The demand for Government goods. on the one hand. and the breakdown of so much general business on the other, have interfered with the development of new types of goods, but notable advances have taken and are taking place, and in view of the experience of the past we can safely look for more of them. So far as it has gone, the temporary cessation of German supplies can be called educative in two directions, causing a certain number of British manufacturers to strain their facilities to produce goods new to them, and causing also a certain number of trade buyers to realise that there are British goods which can, even with advantage, be substituted for purposes for which it had been supposed that only German goods could serve. The instances might have been more numerous had purchases from Germany been larger in the past. At all events, the cases should prove quite numerous enough for the German liking, and when the Germans return to business the occupation of some of their old strongholds by British competitors is a factor they will have to face.

In some of the trades of this country "foreign" competition and "German" competition have been synonymous terms, and the German has been for ever present as a spectre.

Except in special and comparatively unimportant instances this is not true of the textile industry. Their labour is, upon the whole, cheaper than ours, and much cheaper in some instances; their hours are longer than ours, but the evidence negatives the suggestion that they execute their work more cheaply, except in the departments that they have made their own and that have been neglected by us. Figures are less to the point than the common facts of experience, and there are probably no figures purporting to display comparative industrial efficiency which ought to be taken without reserve. The fact that German competition is not the universal bugbear speaks for itself. The small quantity of German goods—specialities apart—imported into this free and open market, and the British lead of 100 millions per annum in exports, give assurance enough that the British industry in its own field occupies a highly superior position. Schultze-Gavernitz, writing twenty years ago, showed that the Saxon and South German cotton spinners employed 5·8 hands per 1,000 spindles. The number has certainly been reduced since, but nothing suggests that it has been reduced to the 2½ to 3½ per 1,000 spindles which is the general rate in Lancashire, where, of course, very much higher wages are paid. The balance is well in the English favour, and extremely little is heard of German cotton yarn in the markets. Mr. Taft's Tariff Board made an effort to tabulate the respective costs of manufacturing wool goods in certain countries. The instances were few in which British and German quotations were obtained for the same fabrics, but in respect of the five worsted samples in which close comparison was made, it was found that the German cost of converting yarn into finished cloth exceeded the British by proportions rising from 24 to 59 per cent., and averaging 43 per cent. all round. The figures were put forward as authentic, and the direction is one in which Yorkshire could be expected to score, although perhaps not thus heavily. On one or two occasions of severe industrial depression in Germany, samples of low woollen goods have appeared in the English market at prices lower than the ordinarily invincible Colne Valley tweed makers could accept, but no considerable consequences have followed upon these brief and infrequent appearances. Carpet manufacturers have made complaint of German dumping. Hosiery yarn spinners have felt the oblique effects of low prices for yarn interchangeable with their own, but in respect of sales at or below cost, the experience of the English textile industry at large is in no sense comparable with that of the steel trade.

Discussion of racial traits, except in so far as they may be revealed in industrial matters, would be outside the scope of this paper. One such may perhaps be found in relation to the machines for which we are indebted to German initiative. German invention has contributed little to the main machinery of textile mills, but there have come from Germany various improved machines for the dyeing and finishing of goods. The machines have come, have functioned duly and sold widely, and yet have commanded few subsequent orders, for the reason that some less elaborate but more direct English mechanician has come upon the scene with a machine of many fewer parts and fittings and capable of still better work than the original. The instance does not stand alone as evidence that the German is not quicker than the Englishman in arriving straight at the essential point. That defect in them has not been remedied by the system of technical education in which the Germans preceded us.

If it be asked whether the German or the English manufacturer shows himself the more enterprising, the answer must have regard to the total size of the industries in the respective countries. Evidently, German enterprise has not led to a larger development than in England. The fact has already been emphasised that the pair have followed somewhat different lines, and this also has to be taken into consideration in drawing any comparison. It is certain that German manufacturers have developed trades which Englishmen have declined, and have worked up business requiring English-made machines and sometimes English materials. It is probably true also that the Germans have followed with more zest the development of certain new processes and certain new textile materials. Those efforts have not been uniformly remunerative, and have not led to any great and striking success in which British industry has not participated to an equal or a greater degree. The Germans may be said to be less shy of far-fetched projects than our own industrialists, but it would be difficult to say in which textile direction their greater venturesomeness has justified itself by results. There are possibly exceptions, but the effect of a large number of inquiries goes to show that, in general, the British textile manufacturer has got the class of business that he wants, and that in his eyes the class carried on by his proximate equal in Germany is in some way less desirable. Thus

one does not find that a spinner able to make a satisfactory return out of relatively coarse yarn has any urgent desire to spin higher numbers; or that the manufacturer with a prosperous trade in cloths of medium construction burns to exchange that line for a trade in goods with very many more threads per inch. Again, the possessor of a fairly steady trade in fancy goods does not necessarily envy the German his more precarious business in articles of a less staple class. The results of war may be to modify some of these valuations, but there is little to suggest that hitherto the German has come off best in the contest of wits.

There is another sense in which the British textile manufacturer has the better end of the stick. His business, as a whole, is done upon more advantageous terms than the German. Credits in general are shorter, producers get along fairly comfortably without the kartels and other mutual interferences which are always being formed and always being dissolved in Germany and Austria. The reason may be that in this country development has been more gradual and natural. The industries have extended, not to exploit artificial opportunities created by legislation, but in response to healthy demand, and this has not invariably been the case in the Protectionist countries.

The inflamed state of public feeling need not preclude mention of one matter for which the English textile industries are patently indebted to German assistance. From the earliest days of which there are records, British weavers have owed something to foreign assistance in the promotion of their export trade. For immediate purposes one need not go back beyond one hundred years. In the early years of the last century foreign merchants, mainly from the Germanic States, began to settle in Manchester, Bradford, Leeds and some other places, to be in immediate touch with the markets whence textiles could be advantageously bought for sale principally in their homeland. The founder of the English house of Rothschild was one of the many who came here upon this errand, and the modern export trade in English textiles grew up largely under foreign hands, and a large part of it is still transacted by heirs and successors whose names bewray their origin. Trading first to the Continent, these merchants and the English ones who profited from their example, extended their operations to all seas. Possessing the knowledge of foreign languages, usages and tastes which the English of the period lacked, they filled an obvious gap in our commercial equipment at a time when the German textile industry was in an embryonic stage. Indisputably they helped British producers to take further advantage of their capacity to manufacture cheaply and largely, and if some familiar charges brought against British traders have no force against textile exporters the credit must in fairness be awarded partly to them. Certainly it cannot be said of British textile shippers that they are reluctant to write or speak foreign languages, or to quote in foreign currency, or to sell cloth by the metre; or that they are anything less than indefatigable in their commercial travelling. In these respects everything has been learned that Germany had to teach.

Remembering that war is compact of uncertainties, and that there are no means of foreseeing the exact situation that will remain when hostilities are ended, anything in the nature of a forecast must be made with diffidence and reserve. One may, however, believe that in all probable circumstances the war will leave unimpaired our real industrial strength – our ability to produce our established products upon the most economical terms. It may be in the power of Germany to cut herself off from our supplies in the future, but that course can hardly be more to her commercial advantage than hitherto, and it cannot be taken without incurring certain penalties affecting her own ability to compete. At least it does not lie within German power to prevent others from taking more of any commodities of which she takes less. Given the ability to produce the most suitable article at the most advantageous price, we shall find a sale for it – if not in Germany, then elsewhere. What holds good upon the one hand, holds also upon the other. So far as German success is founded upon real strength, it can be counted upon to renew itself after the interval, albeit under certain difficulties and after competitors in this and some other countries have gained experience in matching German goods. Labour, it may be, will possibly be dearer in Germany after the war, and taxes conceivably heavier. These influences may be countered by some affecting our own side, and evidently dogmatism upon the point would be wholly out of place. Perhaps upon both sides we may look rather for the change than the extinction of trade, and we may believe that the British industry is financially better able to carry the burdens of war than the German, and is more likely to attach to itself trade hitherto German than is the German industry to carry away business hitherto British.

There are limits to the specifically German trade that we want, and there are influences, other than the political or sentimental, tending to diminish that trade by diverting demand from the articles which cannot be got, and establishing in sale others of which the supplies are procurable. These influences must become more marked as the war wears on and the need for replenishment arises. The duration of the war will in part govern the advantages derived from keeping open shop while the competitor is closed, and its duration, apart from an outcome which can only be called inevitable, must also, for some years after the close, affect German capacity to carry on business. Their own particular trade is of more moment to English manufacturers than is German, and it is for quite other reasons than the prospective effect upon German commerce that our manufacturers exhibit lively interest in the question of when this war will end.

DISCUSSION.

THE CHAIRMAN (Lord Rotherham), in opening the discussion, said he agreed thoroughly with the various arguments and considerations which had been advanced by the author. For instance, Mr. Hunter said that in the production of fine cotton yarns Germany was far behind Great Britain. Our pre-eminence in that class of trade was due very largely to the skill of the operatives who were engaged in it; indeed, there were some who thought that that skill was, in the case of certain families, almost hereditary. He agreed also with the author in regard to the advantage which Lancashire had in the matter of climate so far as the spinning of cotton yarns was concerned. Everybody did not think that the climate of Lancashire was as agreeable as that of some other counties, but for the particular purpose of cotton spinning it had its advantages. Mr. Hunter had said that not only was Germany behind us in the matter of spinning fine cotton yarns, but she was also behind us in the spinning of alpaca and mohair yarns, and bright-haired yarns generally. Germany was a very big buyer of such lustre yarns, and also of the fine cotton yarns; he thought she was a bigger buyer than the statistics of the author indicated, because he believed that many exports from this country, which were destined ultimately for the German market, did not figure in the Board of Trade returns amongst the exports from England to Germany, as they passed through some other country. For instance, a good many such exports passed through Holland, and our exports to Holland would not be nearly as large if it were not for the fact that that was a means of access to some of the German markets. He also agreed that labour was much better remunerated in the English cotton trade than it was in the cotton trade of other European countries, but it must not be supposed that because higher wages were paid therefore the cost of labour as an element in the production of cotton fabrics was proportionately higher. The fact was that labour in this country was, as a rule, much more efficient than it was elsewhere; and it was, from that point of view, possible to pay higher wages to the individual and yet to have a lower labour cost so far as the ultimate production was concerned. He believed that that was so very largely in connection with the cotton trade. The author, in the course of the paper, alleged that it was the desire of cotton spinners as a rule to spin coarse counts rather than fine counts. He (the Chairman) had not noticed himself so keen a desire in the matter of coarseness or fineness of the counts as in the matter of the profit attaching to the production of those yarns. He thought the chief desire was to make a profit, and if a spinner could make more profit by spinning the finer counts than by spinning the coarser counts, or *vice versâ*, he would do so. There was one kind of business which had not been referred to by the author, and which was not altogether foreign to the subject of the paper, namely, the manufacture of artificial silk. That was a trade in which undoubtedly Germany had taken the lead, but he was glad to know that Great Britain had also made substantial progress in that particular trade during the last few years. For one thing, legislation had been a very serious hindrance up to a point, because industrial alcohol was required in that trade, and alcohol, some time ago, whether used industrially or individually, had been subject to a very heavy tax. By a piece of enlightened legislation, however, industrial alcohol had been, under certain conditions, relieved from that tax, and, inasmuch as it was the raw material in the case of the manufacture of artificial silk, that relief gave a much better chance to the artificial silk industry in this country, and the results had redounded very considerably to the advantage of that industry. In the matter of raw materials Great Britain was very much better placed at the present time than Germany. There was an abundance of raw cotton here, whereas in Germany there was a shortage, and in order to supply that shortage there had been a transaction in regard to the transfer of some ships from German ownership to alleged American ownership, and it was intended to send from America some cotton shipments in some of those vessels. The outcome of that would be seen in a few weeks, and he did not wish to say more on that matter, but he thought it was a proof of what he said that Germany was very much more in want of raw cotton than this country was. Then in regard to wool, he believed that British spinners and manufacturers were infinitely better placed than those in Germany. He did not suggest that wool and worsted spinners in this country had as much raw material as they would like, owing to cargoes being hung up in the docks and

round the coast, but there was a veritable famine in Germany in regard to some qualities of wool which were required there. He agreed thoroughly with the suggestion made by the author as to the educative effect of the desire which at present existed to capture German trade, but German trade could not be captured successfully except by the closest study and consideration.

Sir Philip Magnus, M.P., remarked that his only connection with the industry was on account of the interest which he had taken for some thirty-five years in the organisation of technical classes, associated with the textile industries, and in which artisans, employers of labour, managers, and other persons might have the opportunity of studying all the complicated details connected with the industries. With regard to the paper, it breathed a very healthy note. It was extremely encouraging, and showed that, notwithstanding many disadvantages which in the past may have been suffered, there was very little fear of our falling back in the manufacture of the important materials with which the paper dealt. He had been very gratified to gather from the author that the country had not suffered from any want of efficiency on the part of those persons who were employed in the industry. It was pleasant to hear that being said at a time when we were so often told that we were much behind our German competitors in the matter of technical education. It was also very pleasing to hear the Chairman remark that one of the advantages which this country possessed over the Germans was the greater efficiency of the persons employed in the manufacture of textile materials. It was extremely satisfactory to know that in every branch of the textile trade the trade of this country was very much greater than that of Germany, and that it was only in silk that we were behind. He would like the author to say why that was the case. There had never seemed to him (the speaker) to be any real reason why Great Britain should not have as valuable a silk industry as cotton or woollen or any other textile industry. He did not think there was any great reason to fear that, even after the war was over, our textile trade would not continue to hold the same preferential position which it occupied at the present time. During the last few months there had been a considerable depression in all branches of the industry, but that depression had occurred even before the war; it began as early as March or April of last year. It had, of course, been accentuated by the war, but he trusted that Great Britain would be able to capture some portion of the present German trade. The author had correctly stated that the trade between Germany and England in textiles had been mutually advantageous and reciprocal, but there was every possibility that after the war the Germans' love for us would not be increased, and that consequently they would be less willing to trade with England. Even if that were the case, he did not anticipate that there would be any great falling off in the textile trade, because the Germans would then be required to get their supplies from some other country, possibly from America, and in American industry there would be a gap which, he hoped, we should be able to fill up, so that the result would be practically the same to the British industry.

Mr. P. M. Evans (Clerk to the Clothworkers' Company) said that as his Company had done a great deal of work in connection with the University of Leeds, he was very interested to attend and hear the paper. He believed the Textile Industries Department at Leeds was one of the best in the kingdom, if not in the world; and with regard to the Dyeing Department, he believed that a great many of the experiments, or some of the work at any rate, in connection with the big question of aniline dyes had been considered and dealt with in that department. The Clothworkers' Company had been very pleased, by establishing those departments, to help in such an important work.

Mr. Frank Nasmith considered the author had done excellently in compressing the amount of matter he had had to deal with in such a small space. There was one point he desired to raise, without being at all pessimistic about Great Britain, and that was the development of one or two sides of the textile industry in Germany, for instance the development of the electrical side. The Germans had gone very much faster ahead in equipping their mills with electrical driving, and had produced excellent results. A British calico printer told him a short time ago that the British calico printers were absolutely beaten in the matter. The Germans had a system of control of their motors by means of which an exceedingly good regulation was obtained. The operative, although he might not know what he was doing electrically, was able to operate his machine and get such a register that the accuracy and finish of the pattern was really remarkable. With regard to the driving of looms, it had been proved that in this country the individual driving of looms was of material advantage. In his visits to Germany he had noticed that the mills there had been better equipped with electric individual driving than those in Great Britain. He would point out that the German textile industry, or certain sections of it, had been forced to specialise. They had not been able to compete to any considerable extent in connection with what he might call the "bread and butter" side of th trade, but had been forced into other things, and they had developed those departments on such scientific lines that they had beaten us, and we should have to learn something from them. He was speaking particularly of the cotton-waste side of the question. He was very glad to see that there had been a very healthy revival in Lancashire in that matter. One thing had struck him in going

into that question, namely, that the German waste spinners did not always employ waste only, but preferred to use short Asiatic staple, Indian cottons, and so on, which gave a sort of new life to the resultant yarn, and produced a very much finer finish than the ordinary low waste yarns did in this country. There was one curious thing he had discovered when he had been working out a paper for a society in Manchester, namely, that, taking the percentages of exports, he found that Germany's biggest market was our least market and that our least market was Germany's biggest market. He was speaking of the cotton trade. That showed that our markets and Germany's markets were complementary rather than competitive.

On the motion of the CHAIRMAN a hearty vote of thanks was accorded to the author for his interesting and instructive paper, to which Mr. Hunter briefly replied, and the meeting terminated.

REINDEER IN ALASKA.*

The introduction of the European reindeer into Alaska was recommended by Professor S. F. Baird in 1851, notwithstanding the fact that the indigenous American caribou is capable of domestication. This suggestion was also made by Townsend in 1867, and in 1892 Dr. Sheldon Jackson, Agent-General of the Bureau of Education in Alaska, introduced a small herd of domesticated European reindeer, which was followed by others. As a result of breeding, their number now reaches 40,000, and has transformed the native people from hunters and fishermen to herdsmen.

The reindeer indigenous to North America are *Rangifer arcticus* (Barren-ground Caribou), inhabiting the extreme north, and *R. caribou* (Woodland Caribou) in the wooded region south of the former. The latter species differs slightly from that of the old world (*R. tarandus*). Apparently no attempt has been made to domesticate it, though it is fertile when crossed with the domestic reindeer; this character is valuable, since the native species is larger and stronger than the imported species, which appears to show signs of degeneration. The present area of undeveloped land in Alaska that would be suitable for rearing reindeer is estimated at 100,000 square miles, capable of supporting 10 million deer. The most suitable region is north of the Yukon River. The reindeer lichen (*Cladonia rangiferina*) occurs throughout the arctic region of Alaska, in the Seward peninsula, in the tundras of the west, and in the mountains of the Alaska chain and of the Alaska peninsula.

Reindeer do not require shelter; in fact, they require no care beyond watching. Almost half of the present herds are in the Seward peninsula, and the remainder are distributed as far as Point Barrow on the Arctic Ocean in the Alaska peninsula, and to Tanana towards the Yukon River. They belong to Eskimos, Indians, and a few Laplanders; the latter were brought over with the animals by missionaries to teach the care of the reindeer. Some herds belong to the Government. The Alaska Division of the U.S. Bureau of Education, Department of the Interior, looks after all the herds, through the masters of the Government native schools.

In 1911 a hundred carcasses were sent from Norne to Seattle, and sold for 75 cents per lb. Up to the present the Alaska markets have consumed all the reindeer flesh which is produced. A dressed carcass averages about 130 lbs. in weight; the butcher buys the dressed carcasses at about 25 cents per lb. The most suitable age for slaughtering the animals is seven or eight years, *i.e.*, after they have been worked for five or six years. The cows are rarely milked in Alaska; any milk obtained is consumed fresh after dilution with water or as cheese; butter is never made, since the fat has a rancid flavour. There is a heavy loss amongst the young animals, owing to the unscientific method of rearing introduced by the Laplanders and the tundra fires, so that the rate of increase of the reindeer is only half that of herds of cattle.

* Abstract of an article by Levi Chubbuck (Office of Farm Management, Bureau of Plant Industry, U.S. Department of Agriculture) in the *Journal of Heredity*, Vol. V., Washington.

EMPIRE NOTES.

The Canadian Pacific Railway and the War.—The services rendered to the British Army and Navy by the railway and shipping companies of the United Kingdom in the present crisis have been many, but the work of the Canadian Pacific Railway Company has also been of the utmost value to Canada and the Empire, both in the transport of troops and goods and in the placing of their great liners at the service of the Admiralty. The rapidity and smoothness with which the troops were conveyed to the various camps and ports on the line of railway, while the arrangements for the ordinary passenger traffic were but little interfered with, are regarded as a triumph of careful planning and arrangement. But the yet more difficult question of freightage appears to have been met with great skill and with a patriotic disregard of cost and trouble. On the declaration of war, the War Office asked the Canadian Government to supervise the purchase and transport of commissariat supplies from the Dominion for the Expeditionary Force in France. This was undertaken by the Minister of Public Works, who consulted, among others, the President of the C.P.R., who placed at the service of the Minister a special traffic representative and twenty of his staff. So well was their work done, and so expeditiously were the supplies sent to France, amounting to about 120,000 tons of freight, that a

cable was received from England asking the senders to "go slow," as the goods were arriving too fast to be properly handled. Moreover, through the expert knowledge of the Company's officials, vessels were chartered on a minimum charter rate at an average freight for oats at 25 cents per 100 lbs., and for hay at $7·50 per gross ton. Owing to the rise in freights on the Atlantic, a saving of close on 50 per cent. in current commercial rates was thus effected. Further, no charge was made by the Company for the use of their docks by the chartered vessels, and all the goods were warehoused free. In the latter arrangement the Allan Line also co-operated. The efficiency and patriotic spirit evinced by the C.P.R. are worthy of all recognition, and further emphasise the unity of the Empire in all its departments, commercial and industrial, as well as naval and military, in this hour of the nation's need.

The Georgian Bay Islands.—It appears that when the boundaries of Upper and Lower Canada were extended, at the time of Confederation in 1867, the Dominion Government retained control of the islands lying off the coasts of the Great Lakes, and ever since there have been difficulties in regard to the title of the land comprised in these islands. This question, so far as it applies to the Provincial Government of Ontario and the Dominion Government—in relation to the numerous islands and islets of the Georgian Bay in Lake Huron—has now been amicably settled. According to a recent cable advice, "Ontario gets practically all the islands, except the Manitoulin group. The islands have now been found to number between 5,000 and 6,000." The Manitoulin group contains the only islands of any size, Great Manitoulin having an area of 1,600 square miles, and the title to the land of this group will be retained by the Federal Government, just as the title to the lands of the three Prairie Provinces and the "railway belt" of British Columbia is vested in the Federal authority. The full title to the other islets will be vested in the Provincial Government of Ontario. There is no question of administration involved. All the islands, including the Manitoulin group, will continue to form part of Ontario for political and administrative purposes, and will be subject to Provincial as well as Federal laws. The only effect will be that persons acquiring land in the Manitoulin group will have to obtain their title from Ottawa instead of from Toronto. The fact that there are some 6,000 islands and islets in the Georgian Bay of Lake Huron emphasises the enormous area of the Canadian lakes and the magnitude of the Dominion.

The Northern Territory and Mr. David Lindsay.—The visit to London of Mr. David Lindsay, the well-known Australian explorer, who has been identified with the Northern Territory of Australia for the past thirty years, has been availed of by the *British Australasian* for an interview, in which there are several points of interest. In regard to the climate, Mr. Lindsay says that "along the coastal belt, which extends roughly about 100 miles inland, it is rather trying, the atmosphere, owing to the proximity of the sea, and the heavy rainfall, which averages 60 inches a year, being intensely humid. Womenfolk in particular find it very trying and enervating, partly because they cannot get domestic help. But it is a remarkable fact that many white men, who have lived within the coastal belt for years, are still hale and hearty, are able to work hard, and seem likely to die only of old age. So, in spite of its humid climate, the country within the coastal belt is quite healthy. It becomes still more so, quite bracing in fact, the further one recedes from the coast; for, some distance inland, one reaches an immense plateau, which rises gradually from about 200 ft. to 900 and 1,200 ft. Unfortunately the country cannot be said to be well watered, except in the coastal belt: that is partly why it has not been more developed, and is so sparsely peopled. But there is a vast subterranean supply, and plenty of water can be obtained by sinking bores from 100 to 400 ft." Mr. Lindsay regards it as a wonderful pastoral country, which, for its successful settlement, only requires vigorous systematic development, by railways, roads, and ports. Speaking as a member of the Royal Commission appointed by the Federal Government some years ago, he says that among the various railway and other projects recommended was the opening of a new port in the Gulf of Carpentaria at the mouth of the Macarthur River, and a railway thence to the Barkly Tableland to connect with the line to Queensland. These and other suggestions have been adopted by the Government. Mr. Lindsay is of opinion that mining for gold, silver, copper, lead, tin and wolfram, has a good future, if the mines are properly developed and transport facilities are provided. "One of the finest deposits of wolfram in the world," he says, "is known to exist there." "The country," he adds, "is very fertile; cotton grows wild and if properly cultivated should prove very profitable, notwithstanding the high cost of labour. It is really an easy country to develop because of the numerous small ports and rivers; and the absence of high ranges renders access to the interior a simple task. Large herds of buffaloes still roam over the fields and swamps of several of the rivers. These are the descendants of the four or five Indian swamp buffaloes which were turned adrift when the military settlement at Port Essendon was abandoned in 1849. They have thriven marvellously, and though over 100,000 hides have been sent to market, thousands of buffaloes still remain."

Indian Post and Telegraph Department.—The Post and Telegraph Department in India may well be regarded as an unqualified success, as recent returns show. In the Post Office the surplus of £30,000 for 1912-13, has grown to £337,000 in 1913-14, while in the Telegraphs there is also a substantial surplus. These results have

been secured without taking credit for unremunerative post offices, maintained for military and political purposes, or for wireless stations and mobilisation telegraph stores. The charges of the Department are stated to be the smallest in the world, which may be accounted for by the fact that the personnel is composed of the lowest class of natives and that the means of communication are mostly primitive. It is interesting to note that what is termed the V.P.P., or "value-payable parcel" system, has been so developed that goods to any amount can be sent under it. If consigned by rail the invoice is posted as a V.P.P., and the consignee is thus enabled to get delivery of the goods, although he may be miles from any civilised station and in the depths of the jungle. The number of postal articles carried has grown to a total of 69 millions. The "value-payable parcels" aggregated 8½ millions sterling in value, while money orders amounted to 36¾ millions sterling, and the total balance in the Post Office Savings Bank is 15½ millions sterling. The success of this Department is a striking proof of the service which the Imperial Government renders to India, and is one of the incidental reasons of the remarkable display of patriotic feeling which that great Dependency has shown.

OBITUARY.

George Norgate Hooper.—By the death of Mr. G. N. Hooper the Society has lost its very oldest Fellow, since he was elected in the beginning of 1850, and has therefore completed sixty-five years' connection with the Society. Mr. Hooper, who has been an invalid for some time, died on January 12th, at Beckenham, in his ninetieth year.

At an early age he became associated with Messrs. Hooper & Co. (originally Adams & Hooper), the well-known coachbuilding firm, of which his father was the principal partner. The firm had a high reputation for building travelling carriages before the days of railways, and supplied carriages to King William the Fourth, Queen Victoria, and King Edward the Seventh. Mr. Hooper took a deep interest in the technical side of his business, and when he became head of the firm he did very much to improve the status of British coach-building. His leading position in the trade led him to serve as a juror at several international exhibitions. The first occasion was at the Paris Exhibition of 1855, and after the completion of his work he read the Society a paper in December of that year, which was practically a report on the British carriage exhibits at Paris. He acted in a similar capacity at the exhibitions in London 1862, Dublin 1865, and Paris 1867, writing the official report on carriages at the last-mentioned exhibition for the Royal Commission. He reported to the Society on the 1873 Exhibition in London, which, amongst other special subjects, included carriage-building. In 1893 he wrote the article on British carriages for the catalogue of the British Section of the Chicago Exhibition.

His experience in Paris in 1855 led him to see the importance of industrial education, and from that time forward he devoted himself earnestly to its promotion, especially in connection with the carriage-building trade. When the Society, in 1873, established its technological examinations, Mr. Hooper acted as examiner for carriage-building, and when, six years later, the examinations were transferred to the City and Guilds of London Institute, he served in the same capacity for some time.

He was one of the founders, in 1881, of the Institute of British Carriage Manufacturers. He presided at the meeting called to found the institute, and was its president for many years. In connection with this institute and with the Company of Coachmakers, of which he was Master in 1874-5, he did much to promote the training of apprentices and workmen in the carriage-building trade. From 1864 onwards the Coachmakers' Company has offered prizes for drawings, and in later years other prizes were provided by the Company in connection with the trade. Mr. Hooper also did good service to the cause of education generally, and was for nearly eighteen years chairman of the United Westminster Day Schools Committee.

He read a second paper before the Society in March, 1890, which included an account of the carriage exhibits at the Paris Exhibition of 1889. He was a frequent attendant at the Society's meetings, and often took part in the discussions, as well as contributing a good many letters to the *Journal*. His keen interest in technical and educational matters continued almost up to the time of his death, and he was in frequent correspondence with the Secretary of the Society on such subjects.

John Francis Sykes Gooday.—The death of Mr. John Francis Sykes Gooday, from pneumonia, took place on January 16th. The greater part of his life was devoted to the service of the Great Eastern Railway Company. In 1898 he was appointed general manager of the London, Brighton, and South Coast line, but he only retained that position for a year, for in 1899 he returned to his old company, of which he became general manager. This position he continued to occupy till 1910, when on his retirement from active service he was made a director of the company. At the time of his death he was also a director of the London, Brighton, and South Coast Railway Company.

Mr. Gooday received a number of foreign orders, and he was formerly lieutenant-colonel of the Railway Volunteer Staff Corps. He joined the Royal Society of Arts in 1892.

GENERAL NOTES.

"Collegium."—*Collegium*, the official organ of the International Association of Leather Trade Chemists, has hitherto been published in Germany,

and its issue to members resident in Belgium, France, and Great Britain is no longer possible. It has, therefore, been decided to publish an issue in Great Britain during the war, and the first number under the new arrangement has just appeared. It contains, among other contributions, an article by Professor Henry R. Procter, on "The Combination of Acids and Hide Substance," a "Note sur le Dosage de l'azote dans le Cuir," by Professor E. Nihoul, of the University of Liége, a "Note on the Analysis of Cube Gambier," by Mr. H. G. Bennett, and "Photomicrography," by Mr. Alfred Seymour-Jones. The Hon. Editor and Hon. Treasurer of the British Section of the Association is Mr. M. C. Lamb, 176, Tower Bridge Road, London, S.E.

MARKET FOR INDIGO IN CHINA.—The American Consul-General of Shanghai reports that indigo is one of the chief imports into China, Germany having been the principal source of supply for about forty years. In 1913 a net total of 42,610 000 lbs., valued at $7,022,571, was imported into China, an increase of 14,359,200 lbs., and $1,576,311 in valuation over 1912. For the first six months of 1914 a total of 22,087,597 lbs. was imported into Shanghai, as against 38,321,598 lbs. for the preceding twelve months. Of the seven firms handling indigo at Shanghai, one is American and six are German. Two leading German houses practically monopolise the trade, and, it is alleged, largely control the matter of market prices. In some instances indigo is shipped direct to Tsingtao, Hankow, Newchwang, Foochow, and Canton, but Shanghai is the chief distributing centre. The manufacturers of indigo have expert chemists attached to the distributing offices of their agents in Shanghai, who study conditions and cater for the racial peculiarities of the Chinese in the matter of colours. It is said that the offices are at present well stocked, and that the war will not interfere with this trade for some time to come. This statement is borne out by the Customs returns for Shanghai for the first six months of this year. The Chinese, however, are striving to produce a satisfactory substitute for foreign indigo, and the claim is made that they have to some extent succeeded.

PROPOSED ANGLO-RUSSIAN BUILDING TRADES AND DECORATIVE ARTS EXHIBITION.—Amongst architects and artists in Russia a desire has been expressed to remove German influence on the architectural and decorative arts in that country and to replace it by British. The matter is being taken up the Russo-British Chamber of Commerce, 4, Gorochovaid, Petrograd, and after the war is over it is proposed to hold, with the co-operation of the Chamber, an Anglo-Russian Building Trades and Decorative Arts Exhibition in Petrograd. It is to be hoped that this movement on the part of our Allies will receive every encouragement from those interested in architecture and the decorative arts in this country.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 27.—HON. JOHN COLLIER, R.O.I., "Portrait Painting—the Technique of the Great Masters." LORD SANDERSON, G.C.B., K.C.M.G., will preside.

FEBRUARY 3.—OCTAVIUS CHARLES BEALE, Chairman of the Australian Manufacturers' Association, "Imperial Industrial Development after the War." GEORGE R. PARKIN, C.M.G., LL.D., D.C.L., Organising Secretary of the Rhodes Scholarship Trust, will preside.

FEBRUARY 10.—F. VINCENT BROOKS, "British Lithography in 1915."

FEBRUARY 17.—ARTHUR WILCOCK, "Decorative Textiles, and the Designer's Relation to the Industry."

FEBRUARY 24.—W. J. ASHLEY, M.A., M.Com., Ph.D., Professor of Commerce in the University of Birmingham, "The Economics of the War."

MARCH 3.—WILLIAM POEL, "Shakespeare's Profession."

MARCH 10.—J. W. GORDON, "Patent Law Reform and the War."

MARCH 17.—H. M. THORNTON, "The Industrial Uses of Coal Gas."

MARCH 24.—LADY LUGARD, "The Work of the War Refugees' Committee."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 11.—CAPTAIN SIR GEORGE DUFF DUNBAR, Bt., I.A., "Tribes of the Brahmaputra Valley." LIEUT.-COLONEL SIR FRANCIS YOUNGHUSBAND, K.C.I.E., LL.D., D.Sc., will preside.

MARCH 18.—LIEUT.-COLONEL A. C. YATE, I.A. (retired), "The Indian Army."

APRIL 15.—M. M. S. GUBBAY, I.C.S., "Indian Trade and the War."

MAY 13.—PERCEVAL LANDON, "Basra and the Shatt-ul-Arab."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 26.—MAJOR E. H. M. LEGGETT, R.E., D.S.O., Managing Director of the British East Africa Corporation, "The Economic Development of British East Africa and Uganda." SIR OWEN PHILIPPS, K.C.M.G., will preside.

FEBRUARY 2.—EDWARD R. DAVSON, "Sugar and the War." LORD DESBOROUGH, K.C.V.O., will preside.

MAY 4.—S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced :—

THOMAS WORTHINGTON, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. THORNE BAKER, "The Industrial Uses of Radium."

FRANK BAINES, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. HULME, "Patent Law."

D. Y. CAMERON, A.R.A., R.E., "Etching."

ROGER FRY, "Post Impressionism in Design."

C. H. SHERRILL, "Ancient Stained Glass."

A. S. E. ACKERMANN, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock :—

May 13.

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock :—

March 30.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

F. MOLLWO PERKIN, Ph.D., F.I.C., F.C.S., M.Inst.P.Tech., "Oils, their Production and Manufacture." Three Lectures.

Syllabus.

LECTURE II. — JANUARY 25. — Low temperature carbonisation—cracking of oils—Motor spirit—Fuel oils.

LECTURE III.—FEBRUARY 1.—Vegetable oils—Raw materials—Sources of supply—Methods of manufacture—Methods of refining—Edible oils—Paint oils.

M. H. BAILLIE SCOTT, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evenings, at 8 o'clock :—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S. "Motor Fuel." Three Lectures.

February 15, 22, March 1.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. F. Mollwo Perkin, "Oils, their Production and Manufacture." (Lecture II.)

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Messrs. J. G. Head and J. Bury, "The Report of the Land Inquiry Committee on Urban Land Tenure."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Dr. V. Cornish, "The Historical and Physical Geography of the Theatres of War."

Actuaries, Institute of, Staples Inn Hall, Holborn, W.C., 5 p.m. Mr. C. H. Maltby, "The Analysis of Life Office Expenses."

TUESDAY, JANUARY 26. ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Major E. H. M. Leggett, "The Economic Development of British East Africa and Uganda."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Muscle in the Service of Nerve." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. 1. Discussion on paper by Mr. A. L. Bell, "The Lateral Pressure and Resistance of Clay, and the Supporting Power of Clay Foundations." 2. Mr. F. D. Evans, "Engineering Operations for the Prevention of Malaria."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. H. Hardwick, "The Romance of London."

Anthropological Institute, 50, Great Russell-street, W.C., 8.30 p.m. Presidential Address by Dr. A. Keith, "The Slav and Allied Racial Elements in the Peoples of Western Europe."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. T. D. Robertson, "Electric Steel-Making Furnaces."

WEDNESDAY, JANUARY 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. The Hon. John Collier, "Portrait Painting—the Technique of the Great Masters."

Literature, Royal Society of, 20, Hanover-square, W., 5 p.m. Miss Alice Law, "The Cult of the Child-Spirit in Modern Literature."

THURSDAY, JANUARY 28...University of London, University College, Gower-street, W.C., 5.30 p.m. Monsieur C. Poupeye, "Belgian Art. Lecture II.—Sculpture."

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. G. Plimmer, "Modern Theories and Methods in Medicine." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. Robbins, "Out West—*viâ* the Canadian Rockies."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Professor A. Gray, "Lord Kelvin's Work on Gyrostatics."

FRIDAY, JANUARY 29...Chadwick Public Lectures, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Dr. F. M. Sandwith, "War and Disease." (Lecture III.)

Royal Institution, Albemarle-street, W., 9 p.m. Mr. D. Clerk, "Gaseous Explosions."

Junior Art Workers' Guild, 6, Queen-square, W.C., 8 p.m. Mr. C. R. Ashbee, "The Teaching of Art."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7.30 p.m. Professor A. Gray, "Lord Kelvin's Work on Gyrostatics."

SATURDAY, JANUARY 30...Royal Institution, Albemarle-street, W., 3 p.m. Dr. R. T. Glazebrook, "Aerial Navigation—Scientific Principles." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,245. VOL. LXIII.

FRIDAY, JANUARY 29, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 1st, 8 p.m. (Cantor Lecture.) F. MOLLWO PERKIN, Ph.D., F.I.C., F.C.S., M.Inst.P.Tech., "Oils, their Production and Manufacture." (Lecture III.)

TUESDAY, FEBRUARY 2nd, 4.30 p.m. (Colonial Section.) EDWARD R. DAVSON, "Sugar and the War." LORD DESBOROUGH, K.C.V.O., will preside.

WEDNESDAY, FEBRUARY 3rd, 8 p.m. (Ordinary Meeting.) OCTAVIUS CHARLES BEALE, Past President of the Australian Manufacturers Association, "Imperial Industrial Development after the War." GEORGE R. PARKIN, C.M.G., LL.D., D.C.L., Organising Secretary of the Rhodes Scholarship Trust, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, January 25th, DR. F. MOLLWO PERKIN, F.I.C., F.C.S., delivered the second lecture of his course on "Oils, their Production and Manufacture."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, January 26th; SIR OWEN PHILIPPS, K.C.M.G., in the chair. A paper on "The Economic Development of British East Africa and Uganda" was read by MAJOR E. H. M. LEGGETT, R.E., D.S.O., Managing Director of the British East Africa Corporation.

The paper and discussion will be published in a subsequent number of the *Journal.*

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

Wednesday, January 27th, 1915; LORD SANDERSON, G.C.B., K.C.M.G., Vice-President of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Dean, Oliver H., A.B., LL.B., 116, East 36th-street, Kansas City, Missouri, U.S.A.

Parris, Hamilton Harcourt, The Croft, Grenville, Grenada, British West Indies.

Taylor, H. Blake, 22, Cromwell-crescent, S.W.

The following candidate was balloted for and duly elected a Fellow of the Society:—

Soule, President Andrew McNairn, Sc.D., Ph.D., State College of Agriculture, Athens, Georgia, U.S.A.

The paper read was—

PORTRAIT PAINTING.

THE TECHNIQUE OF THE GREAT MASTERS.

By The HON. JOHN COLLIER.

It is very difficult to learn anything about the technique of the Great Masters of portrait painting. One has plenty of anecdotes about their habits and manners (which were often somewhat unsatisfactory), but hardly anyone condescends to tell us how they painted.

It is possible, however, to pick up a hint here and there, and something may be learned by a mere inspection of their works. At any rate, in the course of my studies I have come across some interesting details, and I have formed certain opinions, which I propose to put forward for what they are worth.

We will not go back to the ancients. No doubt excellent portraits were painted in classical times, but we do not know enough about them to discuss them with any profit.

I will also pass over the Middle Ages, and come at once to the Great Masters of the Renaissance. Of these one of the greatest is Holbein, who in manner is still somewhat mediæval, although in date he belongs to the early Renaissance. His portraiture is apt to be a little stiff and somewhat lacking in charm, but, having made these reservations, we can give it our profound admiration. His drawing and modelling are extraordinarily subtle, and his grasp of character prodigious. He seems to give one more insight into his sitter than almost any other portrait painter even the greatest. As for his method there is, unfortunately, no documentary evidence; we must find it out for ourselves. He made a very careful preliminary drawing on paper, which was transferred by tracing to the canvas or panel, generally the latter. He did not depart from this drawing in any essential, although he often slightly improved on it. Many of these drawings have come down to us—they are of extraordinary delicacy and accuracy. Having made this tracing, he surrounded all the important contours with a very thin dark line of paint. The subsequent work never entirely obliterated this thin line. It can only be seen by minute inspection, but it is to be found in all his pictures. He probably began with a light underpainting in monochrome, as was the practice of the Van Eycks, but of this we cannot be certain. The paint was always thin and smooth, and highly finished. All the details, whether of dress or background, are rendered with the utmost care. Any pattern is given in its completeness; he never adopts the practice of later painters of indicating pattern where the light catches it, and losing it in the shadows. It is always there, although so delicately rendered that it seems lost in places. There is no focussing: the head is not thrown into artificial relief by blurring or suppressing the accessories, and yet everything takes its place. The head is so lifelike that it is never overpowered by the surrounding detail. As you fix your eye on any part of the picture you can see it sharply defined (as you do in Nature), but you are never worried by this, as there is no over-emphasis. You are not forced to look at comparatively unimportant details, but you can do so if you like, and find them true to life.

One consequence of this is that the picture looks right from almost any distance. It can be peered into quite closely or viewed as a whole from some way off. In neither case does it suffer.

I rather dwell on this as it is a characteristic of all early work. It was only the later painters who invented a sort of shorthand so that the picture can only be properly seen at a certain distance. When looked at nearer than this distance it seems merely a mass of blurs and smears. This has a charm of its own, for it looks, and is, so masterly. The effect seems to be produced by such strange and inadequate means. But to me there is great pleasure in being able to look closely into a picture and to enjoy the delicacy and precision of its detail.

The freer and more summary method is to be seen at its best in the later works of Velasquez and of Rembrandt. These have to be looked at from a considerable, but never from an excessive, distance. In the case of large works, such as "Las Meninas," it is about the distance at which one would naturally stand in order to take in the whole picture at a glance. Many modern artists go much further than this. Even works of a moderate size have to be looked at from the end of a large gallery to seem at all coherent, and even then—but I will not pursue this somewhat painful subject.

To return to the earlier masters, it is only when we get to Titian that we find any variety of texture and any play of brush work, and even with him it is not very marked. Titian's portraits are very elaborate, but there is a certain suppression of detail and a greater breadth of effect than is found in any earlier work. Titian's pictures seem to have been built up by a very slow process, and his portraits are probably no exception to this rule.

Here is an account of his method. It has come down to us through Boschini, who knew the younger Palma, whose father had received instruction from Titian himself. The pictures were first laid in very solidly with only four colours, a red earth (possibly venetian red), with white, black, and yellow (the yellow was probably yellow ochre). There was no blue; but black and white make a bluish grey, which would be sufficient to indicate this colour in the first painting.

Boschini speaks of four pencillings which were done in this way, and then the picture was put aside for several months. When he took it up again he first amended and corrected all the forms. He then finished very laboriously with continual glazings, and also with rubbings of opaque colour frequently applied with the finger instead of with the brush. "In this way he gradually gave to his works that bloom and perfection of rich surface and that fulness of colour in which his paintings surpass all others," as Boschini justly observes. The essential point about this method is that it is so indirect. The painting was first executed in very dull colours, and the full effect was only arrived at by a protracted series of glazings and scumblings. In one form or another this indirect method was a very favourite one with the older masters, and indeed with many later ones. Sir Joshua Reynolds followed fairly closely on Titian's method, except that he speeded it up a good deal, and his first paintings were with a still more restricted palette; and up to quite modern times some kind of under-painting approaching to a monochrome has been very generally adopted. But of late this indirect method of painting has been entirely abandoned. I do not know any modern painter who practises it.

It seems rather absurd to criticise adversely a method which, in Titian's hands, has given us some of the finest paintings which the world has ever seen; but I certainly think that for portraiture a more direct technique is preferable, and, indeed, this preliminary underpainting was by no means universal even with the old masters. I do not believe that either Velasquez or Rembrandt made any approach to a monochrome preparation.

We have seen that Titian was the first great painter to make much use of texture and of varying surface in his painting. Before his time the surface was uniformly smooth. It is quite possible to suggest a rough texture on a smooth surface, as we can see any day in photography; even a smooth shiny photograph can perfectly represent a wrinkled skin or a rough-cast wall, and what a photograph can do a picture can do, but it involves a great deal of labour. In skilful hands a certain roughness of paint can represent a rough surface as truly as, and much more expeditiously than, the minute alterations of light and shade which convey the appearance of texture in a photograph or in a smooth painting. That all varieties of surface can be represented by appropriate brush work was most fully realised in the later work of Rembrandt. Since then many artists have essayed it, but none with his mastery. Velasquez had also a great power of brush work, but in this he did not equal Rembrandt, though in many other qualities of portraiture I think he surpassed him. I hold that Velasquez and Rembrandt carried the art of portraiture—at least, male portraiture—to the highest level it has ever attained. They were both so indifferent to female beauty that their portraits of women, however masterly, are quite lacking in that essential charm which is given so wonderfully by the great English school of the eighteenth century.

I have tried hard to discover any authentic testimony as to the methods of Velasquez; but, as usual, we have to rely more on inspection of his works than on any contemporary records.

Señor de Beruete, a distinguished Spanish painter, who made a lifelong study of Velasquez, and has written an admirable book upon him, is the best authority I know on the technical side. According to him, Velasquez painted on a red priming in his early work; this gradually changed to a neutral grey in his later style. The impasto of this priming becomes less and less—towards the end it only just covers the canvas, the grain of which is moderately fine even in big pictures. In the "Bacchus" the priming was reddish There are places, especially round the figures and accessories, where this priming has never been covered; so instead of working his figures into the background each part was painted separately, carefully following the drawing. In his later period he became presbyopic, so not being able to see close he had to get further and further away from his canvas, which made his execution more summary. In his latest pictures he used very fluid colours, in some places only floated on, as in water-colours, and there is no impasto save in the head and hands. So far I have followed Señor de Beruete, but I disagree with this dictum. Velasquez used impasto freely enough in the draperies, even in his latest style. I also disagree as to the brushes used by Velasquez. De Beruete says that he always used round brushes, and that there is nothing in his pictures to indicate that he ever used flat ones. I am quite convinced that there are many broad sweeping passages in the master's work that can only be rendered by broad flat brushes. It is interesting to note that Palomino, who wrote only sixty-four years after the death of Velasquez, states that he painted the portrait of Admiral Pulido y Pareja with

exceptionally long brushes, in order to get more vigour and relief; De Beruete entirely rejects this testimony—I think on insufficient grounds. He also denies the authenticity of the portrait of the admiral in our National Gallery, and ascribes it to Mazo. Here, again, I entirely disagree with him. It is a magnificent portrait, well worthy of Velasquez, and very much above the high-water mark of Mazo. With regard to the long brushes, it is true that they must have been abandoned by the time he painted "Las Meninas," a much later work. This picture is an invaluable document as to the practice of Velasquez. He is standing up to his easel with quite a small round palette in his hand, and the brushes are round and of very moderate dimensions; but then he is probably supposed to be just putting the finishing touches to his picture. It is absurd to imagine that he would paint the broader passages of such an enormous canvas with such little brushes. The colours on the palette are given by De Beruete as vermilion, white, terre de Seville, and carmine; and there are indications of three or four sombre tones, which may be blacks or browns. There seems no trace of the blue and yellow that he must have often used.

The room is a big one, very lofty, and lighted from the side by high narrow windows. As he was painting the little princess and the maids of honour, it has been supposed that this was not his usual studio, but merely a room in the palace used for the occasion. I think myself it was very likely his ordinary painting room; it seems well adapted for the purpose, and there are many pictures on the walls, such as artists accumulate in their studios. In any case, this is the room in which he painted what was perhaps his masterpiece. At the risk of wandering a little from my immediate subject, I may mention that one of the great qualities of this picture is that for the first time in art an effort has been made—and an extraordinarily successful one—to give absolute truth of light and shade; and more than that, to give the effect of atmosphere that pervades all natural scenes. For the first time in art a room has been made to look like a real room, with the figures in it bathed in a real atmosphere and lit up with the light and shade of Nature.

This is a very extraordinary achievement. Some of the Dutch painters, such as De Hoog and Vermeer, have given much the same impression of truth to Nature in the relation of figures to their background; but it is a very rare quality in painting, and no one has done it quite so well as Velasquez. It is occasionally essayed in modern times, but rarely with complete success. The best example that I know is "A Venetian Interior," by Sargent. This is a very wonderful work, but by the side of "Las Meninas" it is a little lacking in simplicity. There is too much virtuosity in the touch, and altogether it is a little too brilliantly dexterous. In looking at it one's first thought is, How amazingly clever! One does not say that in front of "Las Meninas."

To return to the actual method of painting employed by Velasquez. In his early period the execution was precise and very hard. He was fond of dark shadows and clear-cut outlines. In the middle period the paint was put on very solidly and simply, but with much greater freedom; the execution could not be called hard, but was definite and precise. In the third period it was freer still; rather vaguer and softer, and much more subtle. In this later period the paint was put on quite thinly in the shadows, so that the texture of the canvas can be seen through—in places it looks hardly more than a slight modification of the thin grey priming. But however thin the shadows were, they were not painted with transparent colour. It was opaque colour, but very thin and liquid. The lights, especially in the flesh, were solid. The whole seems floated on to the canvas very delicately and subtly, but with an extraordinary economy of labour. At the end certain accents, such as the dark of the eyes or the shadow of the nostrils, were put on with the scratchy touches of a small brush, and the painting was finished—at least, so it looks at the proper distance. Seen near it is just a few soft smears and a dark scratch or two. But then these smears are so wonderfully true in tone and in form. When one has achieved a mastery such as that painting seems surprisingly easy.

Velasquez was not afraid of making alterations when necessary; but one of the characteristics of his work seems the sureness of his intention His pictures are conceived, as a whole, from the very beginning, and yet he made no studies or preliminary sketches—at least, practically none have come down to us. Through all the three periods his colouring remains simple and subdued, but extraordinarily harmonious. It is mostly in the key of grey.

I think this is all that can be said with any safety as to the methods of Velasquez. The case of Rembrandt is still more difficult. He seems to have worked in a studio with a very

small window, so as to get the powerful effects of shadow in which he delighted. His chiaroscuro is far more artificial than that of Velasquez. It is extraordinarily skilful, but to me it is too arbitrary to be quite satisfactory. Again, the warmth of his colouring is unnatural, although very pleasing. He was a great colourist, but somewhat lacking in variety. He affects almost exclusively the browns, reds, and yellows, but within this limited range his mastery is supreme. The extraordinary success of Rembrandt in the key of brown has led many artists to imitate him in their colour-schemes, but mostly with disastrous results. For most painters the greys of Velasquez are much safer, besides having the advantage of being truer to Nature.

The early work of Rembrandt is careful and precise, but it is not hard like that of Velasquez. The execution is smooth, and there is no attempt to render texture by brush work. The best example of this early period is the celebrated "Lesson of Anatomy," at the Hague, painted when he was twenty-six—an extraordinary masterpiece for so young a man

In spite of the size of the picture the execution is so delicate that the hairs at the end of a moustache are drawn separately with a fine brush, and yet the effect is broad and forcible. This force is gained by a powerful effect of light and shade, and by a certain breadth of treatment, but not by any vigour of handling. The hands in this early work are particularly good. In his later style Rembrandt was apt to be careless in this respect.

In his middle period, the beginning of which is marked by the so-called "Night Watch." the most amazing of all his pictures, his execution has become much more masterly. Dr. Bode speaks of a soft buttery impasto as characteristic of the works from about 1645 to 1659, and in contrast describes the painting of the heads in "The Syndics" of 1661 as loose and granular, and with some exceptions I think this can be taken as fairly descriptive of the methods of his middle and latest periods.

It is in this third or latest period that Rembrandt's full mastery over the resources of oil paint is achieved. I am convinced that he then painted on a dark ground; the paint was put on thickly and so manipulated with stiff brushes as to give any variety of texture he required. He would sometimes dig right through the paint to the ground below. In this manipulation of the actual texture of the paint Rembrandt is supreme — no one has ever done it so well before or since.

The portrait of an old man in our National Gallery, painted in 1659, is a fine example of this vigorous and masterly brush work.

There is another Dutch painter, Franz Hals, whose brush work has been extolled almost as much as Rembrandt's. It is certainly supremely dexterous, but it is not so really masterly. Rembrandt, by the texture of his paint, actually renders the wrinkled skin of old age. Hals does not attempt to do this. He merely excites our wonder by showing with how few touches he can produce the illusion of a finished painting. The method of Hals appears at first sight to be extraordinarily simple. He seems to be more a draughtsman than a painter. The shadows are put in with clear, decided touches, and modelling is less thought of apparently than the accurate placing of the accents which mark the features. The hair is painted with great coarse strokes, like an enlarged drawing. Then the colour of the heads is mostly poor, hardly more than one even tone with brown or black shadows. He seems to have kept all his fine colouring, and it was sometimes very fine, for his costumes and accessories. At least, this is how I used to think of Hals' work, but of late I have begun to appreciate it better, and to find all sorts of very delicate subtleties of modelling, and even of colour, where before I had only been struck by a certain coarseness of effect. And I have lately come across a contemporary account of his work which shows that the method was not quite as simple and as straightforward as it seems.

According to Houbraken, Van Dyck said of Hals: "He had never known anyone who had such power over his brush that after laying on the portrait he could render the important touches in the lights and shades and in the right place with one stroke of the brush without blending or changing; the first stage in his portraits had the effect of an indeterminate blur, then followed the broad brush strokes as if the master said, 'Now the painter's handwriting must come in.'"

This sheds a flood of light on the technique of Hals. I certainly never suspected that the first stage of his portraits resulted in an indeterminate blur, but I can understand how valuable this preparation for the final decided touches would be. No doubt it was this that gave the subtlety, whilst the firm touches gave the dash and vigour.

This is how I conceive Hals to have painted. He used a smoothish canvas with a light yellow-brown priming. One can see this priming in

the head of a man at the National Gallery. It forms the ground colour of the hair. He, no doubt, drew in his picture carefully but very broadly. Then came the indeterminate blur which gave the subtle modelling with the merest indication of the features. This was left to dry. Then at the final sitting a very thin coat of the flesh colour was passed over the whole face, broadening and simplifying but not obliterating the modelling given by the blur. Then on the wet paint came the decided touches—"the handwriting"—which gave with the fewest possible strokes the drawing of the features and the matchless vivacity of the expression.

I have dwelt so much on the method of Hals as it is the foundation of what is best in modern portraiture. Mr. Sargent's work is curiously reminiscent of Hals. He has the same admirable vivacity of pose and of expression; the same resolute determination that the finished picture shall have all the freshness of a sketch; the same apparent economy of means, the perfection of the few touches that give all the illusion of elaborate finish when seen at the proper distance.

Of course, in one branch of his art Mr. Sargent has far excelled his master—Hals seldom painted women; when he did they had no charm. Mr. Sargent has painted many beautiful women very beautifully. Nearly all that is most vital in modern portraiture is derived from Mr. Sargent, and through him from Franz Hals.

In some ways I regret that it should be so. It is a fine method, though not, I think, the very finest. At any rate, it is a pity that so many other fine methods should be unrepresented in modern art. For instance, I have been longing for some time for a movement of "back to Holbein." I can imagine no more wholesome corrective of the modern tendency to sloppiness and haste, but I regret to say that I can see no sign of it.

Rembrandt is too elusive to be followed with any profit, but the methods of Velasquez are so simple that I think they might be imitated with some hope of success.

Then there is another Dutch painter who produced masterpieces by sheer force of competent industry. There was no secret about the method of Van der Helst. It just consisted in painting everything as well as he possibly could in an absolutely straightforward manner. Surely some of us could do the same, if we would but take the trouble? We should have to take a great deal, for there are no short cuts in the laborious method of Van der Helst; but no one can look at his great picture of the Banquet of the Civic Guard without feeling that a method which produced this masterpiece is not to be despised.

So far, portraiture has been very uncompromising. Painters have never flattered their sitters. They have endeavoured to render them just as they are. The great Velasquez never flattered, although as a Court official there must have been some temptation to do so. But when we come to Rubens and Van Dyck we see a distinct endeavour to be polite to their aristocratic sitters. Velasquez never succumbed to the atmosphere of the Court, but they did, Van Dyck perhaps more than Rubens, being the weaker man. From their time onwards portraiture has never been quite free from the vice of over-politeness except in quite modern days, when we run very distinctly to the other extreme. I sometimes wonder why people go on having their portraits painted, as most modern artists are so singularly unkind to their sitters.

Both Rubens and Van Dyck were men of extraordinary gifts, but they were both courtiers and both over-prolific, and their art suffered accordingly. The essential point of the technique of Rubens is his insistence on the transparency of the shadows. He is reported to have said: "Begin by painting your shadows thinly; be careful not to let white insinuate itself into them—it is the poison of a picture except in the lights; if white be once allowed to dull the perfect transparency and golden warmth of your shadows, your colouring will no longer be glowing, but heavy and grey. The case is different in regard to the lights; in them the colours may be loaded as much as is thought requisite. It is necessary, however, to keep them pure. This is effected by laying each tint in its place, and the various tints next each other, so that by a slight blending with the brush they may be softened by passing one into the other without stirring them much. Afterwards you may return to this preparation and give to it those decided touches which are always the distinctive marks of Great Masters."

From this it is obvious that there was no monochrome preparation. The painting from the first was fully coloured. Rubens used a white ground which shone through his transparent shadows and gave them a wonderful warmth and luminosity—often too much. His touch is very liquid, so that he obviously used a very fluid medium. The portraits are altogether a little artificial, but they are very dexterous, and have a most agreeable swagger. He had,

as I have said, a tendency to flattery, in pursuit of which he often made the eyes too big—a very fatal fault. Holbein, on the other hand, had a slight tendency to make the eyes too small.

Van Dyck's work at his best is sounder than that of his master. He made less use of transparent shadows, thereby getting much more truth of tone. He was quite as fine a colourist, and, on the whole, a better draughtsman. His technique is to be seen at its best in the portrait of an old man in our National Gallery who is now called Cornelius Van der Geest. He was justly proud of this portrait, and used to take it about with him as a specimen of his work. The brush work is very dexterous, much more so than in most of his portraits.

Both Rubens and Van Dyck adopted the pernicious practice of making use of pupils and assistants.

Here is a contemporary account of Van Dyck's usual routine :—

" He never worked longer than one hour at a time on each portrait. When his clock told the hour he rose and made a bow to the sitter, as much as to say that enough was done for that day; after which his servant came to prepare fresh brushes and palette, while he received another person to whom he had given an appointment.

" After having lightly sketched the face, he put the sitter in an attitude that he had previously meditated, and with grey paper and black and white crayons he drew, in a quarter of an hour, the figure and drapery, which he arranged in a grand manner and with exquisite taste. He then handed over the drawing to skilful persons whom he had about him to paint it from the sitter's own clothes, which were sent on purpose at Van Dyck's request. The assistants having done their best with the draperies from Nature, he went lightly over them, and soon produced by his genius the art and truth which we there admire. As for the hands, he had in his employment persons of both sexes who served as models."

I need hardly point out the vices of this system. The marvel is that the work should be as good as it is, but in the last years of his life in England, to which the above description applies, he painted a number of very indifferent portraits. His earlier work during his stay at Genoa, when he probably painted his pictures himself, without much aid from assistants, is very much finer.

The next really important group of portrait painters is to be found in the great British School of the eighteenth century, when Reynolds, Gainsborough, and Romney were all painting at the same time. In their conception of portraiture this group was much influenced by Van Dyck. They had the same tendency towards a sort of courtly elegance, and they were much inclined to flatter their sitters. As painters of men I should judge them distinctly inferior to Van Dyck, but as painters of women much superior. Van Dyck, with all his elegance, never quite got the charm of womanhood—indeed, many of his female portraits are stiff and almost wooden.

But our three great painters had an extraordinary feeling for the grace and beauty of women and children. Never have they been more charmingly portrayed.

With regard to technique, Sir Joshua certainly aimed at reproducing the Venetian manner and colouring, and at his best he was very successful in so doing; but he was always making rash experiments, and was continually varying his practice, with often disastrous results to the permanence of his pictures.

Here is a description of his early practice by an amateur painter who was admitted to his studio :—

" On his light-coloured canvas he had already laid a ground of white, where he meant to place the head, and which was still wet. He had nothing on his palette but flake-white, lake, and black, and without making any previous sketch or outline he began with much celerity to scumble these pigments together till he had produced, in less than an hour, a likeness sufficiently intelligible yet withal cold and pallid to the last degree; at the second sitting he added, I believe, to the other colours a little Naples yellow."

He must have used a fuller palette for the subsequent sittings, but that is not mentioned. It *is* mentioned that this particular picture " very soon faded, and soon after the forehead cracked, almost to peeling off, which it would have done long since had not a pupil repaired it."

This was in 1754. There is a letter of Sir Joshua's in 1770 describing his practice then, when he was forty-seven years old.

" I am established in my method of painting. The first and second paintings are with oil of copaiba (for a medium), the colours being only black, ultramarine, and white. The second painting is the same. The last painting is with yellow ochre, lake, black, and ultramarine, and without white, retouched with a little white and the other colours." In spite of his saying that

he was established in his method of painting, he was continually altering it, but he kept to the main lines—a very cold and bluish preparation, corrected afterwards by warm glazes. As for medium, besides the oil of copaiba, he often used megilp (a mixture of oil and mastic varnish), and a varnish made by dissolving wax in Venice turpentine. He was very fond of this wax varnish, and frequently went over his pictures with it after they were finished.

I may add that he adopted Van Dyck's pernicious system of having a sort of picture manufactory. He had a big house in Leicester Square, with numerous rooms for his pupils, copyists, and drapery men. His pupils served also as models for hands and draperies. With the aid of his assistants he turned out his pictures at a surprising rate. In one year he produced 150 works — about half of what Gainsborough produced in the whole of his life. But Gainsborough had no manufactory - no assistants; his pictures were entirely the work of his own hands. Gainsborough's method was strikingly original. Here is an account by an eye-witness: "I was much surprised to see him sometimes paint portraits with pencils on sticks full six feet in length, and his method of using them was this: He placed himself and his canvas at a right-angle with the sitter, so that he stood still and touched the features of his picture exactly at the same distance at which he viewed his sitter."

Velasquez is said to have tried this method of ong brushes, but did not persevere with it. Gainsborough probably did. I think it is habitual in his later work. It gives a delightful sketchiness of execution, which sometimes degenerates into mere scratchiness. He made many preliminary sketches for his pictures, sometimes mere scribbles, but at other times fairly elaborate studies. For full-length portraits he would first make a small sketch of the figure in oils before beginning to work on the full-sized canvas. From this sketch he would lay in the complete figure with all its accessories, and then finish from the sitter.

As a portrait painter Gainsborough had many defects. He was not a good draughtsman; his figures are often very faulty in proportion, the hands are habitually badly drawn, and he had a peculiar way of representing eyes — he made them very expressive, but their form was distinctly not that of Nature; also there is rather a fatal family likeness in a good many of his female portraits. And the men's portraits are often flimsy and weak. But no painter has had a greater measure of that very elusive quality, charm. His portraits of women are the most charming in the world.

He was a very fine and original colourist, and a master of decorative arrangement. Altogether a most delightful painter, but with limitations.

There is a very interesting appreciation of Gainsborough's work by Reynolds in one of his discourses. He says: "It is certain that all those odd scratches and marks which on close examination are so observable in Gainsborough's pictures, and which even to experienced painters appear rather the effect of accident than design, this chaos, this uncouth and shapeless appearance, by a kind of magic at a certain distance assumes form, and all the parts seem to drop into their proper places, so that we can hardly refuse acknowledging the full effect of diligence under the appearance of chance and hasty negligence. . . . His handling, the manner of leaving the colours—in other words, the methods he used for producing the effect—had very much the appearance of the work of an artist who had never learnt from others the usual and regular practice belonging to his art."

Sir Joshua evidently felt that Gainsborough ought not to have been a good painter, but he had to acknowledge that he was one; indeed, he goes on to say: "It must be allowed that this hatching manner of Gainsborough's did very much contribute to the lightness of effect which is so eminent a beauty in his pictures."

As for Romney, I have been unable to find any contemporary record of his technique.

We will now consider Raeburn, who marks the transition from the eighteenth to the nineteenth century, and whose work has had a surprising vogue of late years. I think myself that Raeburn is a somewhat overrated painter; but he has had undoubtedly a great influence upon modern work. His method is essentially that of Franz Hals. It is extraordinarily direct and very masterly; but the characterisation is not nearly as good as that of Hals, and he mostly misses the extraordinary vivacity of expression that distinguishes the Dutch master.

As in the case of the great painters of the eighteenth century, there is a strong family likeness in his portraits. There are one or two of very different gentlemen which seem almost identical. He was essentially a mannerist, although the manner was very strong and good. Fortunately we know something about his practice. Here are some notes collected by Sir

Walter Armstrong in his monograph on Raeburn:—

1. He seldom kept a sitter more than an hour and a half or two hours.

2. He never gave more than four or five sittings to a head or bust portrait.

3. He did not draw in his subject first with chalk or charcoal, but directly with the brush on the blank canvas.

4. Forehead, chin, and mouth were his first touches.

5. He placed the easel behind the sitter and went away to look at the picture and sitter together.

6. A fold of drapery often caused him more trouble than the build and expression of a head.

7. He never used a maulstick.

From these notes we gather that Raeburn's method was singularly direct. He certainly made no kind of preparation. He aimed at putting every touch on the canvas as right in tone and drawing as he could get it. If he were successful in this it remained unmodified. If it were unsuccessful it had to be redone. I do not think he repainted the whole head each time, as was Whistler's practice. If a touch was wrong it was repainted firmly and solidly; if it was right he left it alone. So that the finished picture is a sort of mosaic of definite touches, each of them apparently put on the canvas with one sweep of the brush. In his earlier works he carried this method so far that his faces look much too hard—as if they were cut out with a hatchet. Oddly enough, Raeburn's work did not become more summary as he grew older, as is the case with most artists. On the contrary, his modelling became much more subtle, and his touch softer and more fused—to the great improvement of his painting.

And now we come to the moderns. I have always considered Millais one of the greatest of modern painters, and I can speak with some confidence of his technique, as I had the privilege of his friendship, and he used to allow me to see him paint.

In life-sized portraits he always put his canvas side by side with the sitter, and walked backwards and forwards the whole length of his studio, putting on a touch, and then looking at it from a distance to see if it was right. If it was not right he would come forward again to modify it; this modification he often did with his finger.

He once said to me, "Get away from your picture till it looks the size of a postage stamp, and then you will see if it is right or not."

He did not draw his picture very elaborately, but he was careful how he put it on the canvas. Having made a rapid sketch of the general attitude, he got to work at once on the head with the full vigour of a rich palette, just rubbing in lightly a little of the background round it. At the end of the first sitting the head looked very much as it did at the end of the final one; he only added accuracy and refinement to it. He was not very particular as to his execution; he wanted his painting to look like Nature, and he did not much care how he did it. As he said once, "It doesn't matter how beautifully a thing is painted, it's no good if it isn't right; it's got to come out. What does it matter how you do it? Paint with the shovel if you can't get your effect any other way."

Millais rather despised mere technique, that is, any very definite method of painting—possibly he despised it too much. Mr. Comyns Carr in his recent book, "Coasting Bohemia," relates how, "One day we were talking of technique, and I remember Millais, who was at the time in some trouble with a portrait that he could not get to his satisfaction, roundly declared that for an artist worth the name there was no such thing as technique. 'Look at me, now,' he said, 'I can't get this face right, and it has been the same with me all through my life: with every fresh subject I have to learn my art all over again.'" It was perhaps this absence of a definite technique which made Millais' work so very unequal, but it helped to give him his marvellous freshness and variety. Each portrait is absolutely individual, and has no trace of that fatal family likeness that we find in mannerists such as Raeburn.

A very different painter was Whistler—a man of great natural ability, but who was too much bound down to his method. He took immense pains, but his great preoccupation was to make people think that he did not take any. No matter how many sittings he had—and he generally had a great many—he always wanted his picture to appear as if it had been entirely painted at one sitting. So each time he went over his whole picture and repainted it afresh. As it is impossible adequately to paint a whole portrait at one sitting, he merely spoilt his work, and neglected the more valuable elements of portraiture in order to attain the quite secondary advantage of an agreeable sketchiness.

In other respects his method was sound enough, and had the merit of extreme simplicity. I have been given some very interesting notes

as to Whistler's technique by a well-known artist who worked for some years in his studio.

"He put the picture side by side with the sitter. The canvas had a grey preparation made with black and white mixed with turpentine. He did not use a palette, but had a table near him, on which he mixed the tones he was going to use. This was a very important part of his practice; before actually painting his picture he mixed with great care a quantity of the tones he would require, such as background colour, floor colour, coat-colour in the light, ditto in the half-tone, ditto in the shadow; flesh colour in the light, in the half-tone, and in the shadow; hair colour in the same way, etc. He had a mixture of oil and turpentine in a saucer standing on the table. Using this as a medium, he covered thinly the whole canvas with these prepared tones, using house-painters' brushes for the surfaces, and drawing lines with round hog's-hair brushes nearly a yard long. His object was to cover the whole canvas at one painting—either the first or the hundredth. When a thing was incomplete, he did not try to patch it; he did it all over again and again, till it was finished, or wrecked, as often happened, from the sitter getting tired or growing up or growing old.

"He would put the mixtures in little gallipots of water round the table, so that he could depend upon taking up the same tone another day.

"For many of his portraits he used a quite black background. He had a square of black velvet nailed on to an easel which he wheeled about. The lighting was always subdued; his sitter posed far away in the penumbra of the studio, and never under a direct light. He said he hated high lights in a picture."

What was best in Whistler's practice was his intense preoccupation with the tones; and be it observed that these very delicate tones, that in his best work are so beautifully harmonious, are put on in the simplest possible way—just ordinary paints carefully mixed, and then put on thinly with a big brush. I think this is a sufficient refutation of the theory that "quality" in painting can only be obtained by broken colour, or by glazing, or scumbling, or other tricks. Whistler's work has a very fine quality, and it is obtained by the simplest possible means. If only he had not spoilt it all by his mania for repainting the whole picture each time, he might have obtained results not so very unworthy of Velasquez, whose method was also completely simple, but far more rational.

And now we come to the greatest of modern portrait painters, John Sargent. Sargent is like the old painters, in that he has a very definite method of which he is completely master. There is very little that is tentative about his work. He knows what he wants to do, and also how to do it—a quality which is very rare in modern art where most of us are fumbling and bungling with no clear aim and no settled method.

As I have said, Mr. Sargent's work is undoubtedly founded on that of Franz Hals. It has the same quality of sureness of touch combined with great delicacy. In this, indeed, he excels his master; there is much more delicacy in Sargent's flesh tones and more refinement of drawing. Also he has a feeling for beauty in which Hals was almost lacking. But there is a vigour and a directness in the older master and a vivacity of expression that even Sargent does not always equal. I feel some diffidence in giving an account of Sargent's technique, as it does not come direct from himself. He wrote to me about it very kindly some years ago, and this is what he said: "As for describing my procedure, I find the greatest difficulty in making it clear to pupils even with the palette and brushes in hand and with the model before me, and to serve it up in the abstract seems to me hopeless. It is less a technical process than an order in which to proceed."

That is, he carries out the painting in a certain definite order. Of course this order is very important, and I do not despair of elucidating it. Mr. Sargent has taught with great success in the Academy schools, and I have been given some notes of his procedure by one of his pupils, which I think are quite trustworthy. This was the procedure:—

"First, a careful drawing of the masses of hair, face, collar, coat, etc., together with the correct placing of the subject on the canvas, with spots giving the exact location of the features. Secondly, using a large brush with plenty of paint, put in the tone and colour of the background as nearly correct as possible, letting the background well overlap the borders of the portrait. Thirdly, a kind of middle tone of the flesh is painted over the whole flesh space—light on the light side, dark on the dark side—painting the tone right into the background (background into flesh, flesh into background, until the effect of the truthful blending or melting of the one into the other is obtained); so with the hair and flesh and hair and background. When this is finished the head ha

something the appearance of a wig-maker's block. Of course, the drawing round the borders of the masses must be very thorough, not only in the pattern of its mass but in the coming and going of the edge—as true to Nature as it is possible to get it. The broadly graduated tone from the light side to the dark must be truthfully expressed. There are as yet no features. With the canvas arranged by the side of the sitter, and going to the full length of the studio, this preliminary painting is carefully tested from the point of view of drawing, colour, and tone.

"It is then carefully noted where the broad tones of the features should be placed in relation to all that has been done. The broad tone, in which may be said to dwell the eye, is then painted into the big middle tone while wet and fresh, being careful to have it right in colour, tone, and drawing, that on the light side differing from that on the dark side exactly as it is in Nature. It will then have the effect of a receding plane.

"As with the eyes, so with the nose—a kind of middle tint between the light and dark side to indicate its form and place; so with the nostrils, again with the mouth and chin, continually viewing the progress of the work from the far end of the studio.

"Then follow the various relationships in tone of the darks, subtly cast shadows and the like, vigorously brushed into the wet paint, and then the lights in their various relationships, until the whole appears to be true in tone.

"This would all be the first day's work. It is left to dry, and on resuming is oiled out carefully and well brushed with a dry brush to remove all superfluous oil.

"The whole picture is then thoroughly criticised, and the same ground gone over in much the same way, using as far as possible the work of the first painting by working thinly over it, never forgetting that the tones must be brushed fearlessly and well, the one into the other (sometimes the light into the dark, sometimes the dark into the light), so that the two fuse together and are felt as a continuation of the same substance."

To these notes I have an important addition by another student, viz., that at the end of the day everything should be brushed together whilst the paint is wet in order to get rid of all sharp edges. So that we are getting somewhat near to the indeterminate blur of Franz Hals—to be followed, of course, by the decided touches which, as Van Dyck said, give, as it were, the handwriting.

The method of Sargent is so predominant in modern art that most of our clever young painters seem to adopt it in some form or other—at least, those of them who have not degenerated into pure freakishness, of which there are, alas! far too many. It certainly has wonderful results in the hands of its originator, but it is a difficult method, and it has this danger — that the cleverness of the painting seems often to attract more attention than the rendering of the personality of the sitter. Indeed, the followers of Mr. Sargent are so desperately anxious to be clever that they often forget to be good. With many of them the method degenerates into mere pretentious sloppiness. Mr. Sargent is a genius, and a genius must go his own way, but those of us who have no genius (and there are still a few left) had better avoid the difficulties with which he plays so easily and so deftly.

DISCUSSION.

The Chairman (Lord Sanderson) said it was usually convenient that the Chairman should initiate the discussion which habitually followed the reading of papers at the Society's meetings, but he desired at once to say that he accepted the office of Chairman on the present occasion for the purpose of listening as an acolyte, and that he was quite incompetent to speak with any authority on the subject. He could only join with the rest of the audience in thanking the author for a most interesting paper, which had, for a time, taken their thoughts away from more exciting but rather painful subjects, and for exhibiting a very beautiful series of illustrations. There was, he believed, a book entitled, "How to Look at Pictures." He imagined that most people looked at them anyhow. He was in ordinary times inclined to frequent the National Gallery, when their energetic lady friends allowed it to be open for inspection; and, quite irrespective of the pleasure of looking at the pictures, he found a good deal of amusement in listening to the observations of other visitors. He had wondered sometimes what the appreciations were of the troops of small school children who came in with a rush, cast themselves down on their stomachs on the floor before some great masterpiece, and began scribbling in note-books. He once heard a man addressing a friend as they stood in front of a certain Baptism in the River Jordan which had been the subject of heated controversy, say, "Don't tell me that Raphael or Perugino ever painted a shoulder like that." He felt inclined to ask very humbly, "What, never?" for even Raphael and Perugino must have had a beginning. On another occasion, in the same room, two carpenters looked

for a moment at the Ansidei Madonna, and one of them said, "That canopy is out of the square"—which he believed it was. But he did not think he ever realised how much additional interest arose from some knowledge of the manner in which pictures were painted until he once had the privilege of walking through the gallery with a Royal Academician and hearing his remarks on the pictures, their various characteristics, and the methods by which the effects were obtained; and he felt sure that the majority of those present, though they might be less ignorant than he (the Chairman), would find that what they had heard that evening would add largely to their pleasure, besides improving their power of criticism. There was one question which had often exercised his mind. Why was it that when looking at certain pictures, for instance, Raphael's portrait of Pope Julius II., or Velasquez's portrait of Admiral Pulido, they felt at once convinced that they were accurate likenesses of the originals, and could they be quite sure that the impression was a correct one? They were not always right in such matters. There were certain aged people, who, they felt convinced, must have been exceedingly handsome when they were young, but he had in some instances been assured that good looks had come with years. He fancied that all they could really be confident of in regard to such matters was that the artist formed to himself a complete and consistent idea of the character as well as the appearance of his sitter, and carried it through in all respects. One remembered the remark of the artist who made the portrait of Francis Bacon, "I had rather paint his soul if I had a canvas worthy of it." And that, perhaps, might supply an explanation of the undoubted want of charm in the female portraits of some of the Dutch masters to which the author had alluded. It was possible that they either could not, or did not, take the trouble to realise the grace of their characters, or possibly they might have allowed their female sitters to get bored, and boredom had a dreadful effect upon the female countenance. A friend of his, who sat for a presentation portrait, remarked to the artist, when he was at last allowed to look at it, "I quite see that this is a very good work of art, but I don't think anyone can say it is the portrait of a handsome man"; upon which, he ruefully declared, the artist at once said that any attempt at alteration would probably spoil the likeness. He (the Chairman) would never have contended that his friend was an Adonis, but a good many of those who knew him thought that neither the likeness nor the picture would have suffered if he had been rather more favourably depicted. He was taking up too much time with what was, after all, mere gossip, and he would only ask one small question of detail, and conclude with an anecdote—trivial, but, he believed, historical. He had been told that after Holbein had once made the pen-and-ink drawings of which they had heard he troubled his sitter no more, and did his colouring from memory without comparing it with the original. That, if true, would account for some peculiarities of his portraits, and it would also have made him a very popular painter with busy men. The anecdote he wished to tell was as follows: It was said that King Edward VII. as a boy was fond of drawing, and rather a proficient. On one occasion, finding a nice piece of paper in the library at Windsor Castle, he devoted himself to producing a work of art. It was being handed about and criticised, when someone looked on the other side of the paper, and found it occupied by a pen-and-ink drawing of the Court Painter of Henry VIII.

Sir Thomas Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc. (Chairman of the Council), in proposing a cordial vote of thanks to the author for his most interesting paper, said that if there was one point in it with which he ventured to disagree it was that artists should go back from the days of Sargent to those of Holbein, because, speaking for the man in the street, he had infinitely more respect and affection for the works of modern artists, as exhibited yearly in the Royal Academy, than for the stiff and unsympathetic system of portraiture which existed in the days of Henry VIII. Nevertheless, he was in full sympathy with the Chairman's remarks as to the educational value of being able to see what were the points of a picture from the artist's point of view. As a very humble dabbler in landscape painting, he could attest the statement that one soon learnt to notice all sorts of things in Nature that one never observed before from the simple process of trying to imitate Nature's scenes. Delicate little indications of light, shade, colour and form, which would have passed absolutely unnoticed in earlier days, caught the eye and appealed to the imagination almost at once after a certain amount of experience in the attempt to delineate Nature as it was seen. It was exactly the same in visiting the Art galleries. He felt it would be an immense advantage to him if he could see, as the painter saw, a little behind the mask of the man and discerned something of the soul that was in him, and if he could really feel with the painter that he was representing a man and not merely an image.

Mr. Carmichael Thomas, in seconding the motion, said a very large number of people knew the author as an excellent and conscientious portrait painter, and a larger number still knew him as a painter of problem pictures. Nobody gave more cause for dissension at the family table than Mr. Collier did in the month of May. The audience also knew him as an excellent lecturer, the paper being full of instruction and humour.

The resolution of thanks having been put and carried unanimously,

The Hon. John Collier, having thanked the audience for the very kind way in which they had received his paper, said the Chairman had asked whether Holbein actually painted his portraits from his sitters. It was quite true that, on the preliminary drawings Holbein made, there were, generally, little notes as to colour and various things of that kind; he carefully prepared his pictures from those drawings and notes, and laid them in broadly with the colours that were required and with a careful outline, but he had not the smallest doubt in the world that, having done that, he had recourse to the actual sitter and finished his picture from the sitter himself. It was impossible for such fine works to have been otherwise produced. He did not suggest for a moment that artists should abandon the method of Sargent entirely for the method of Holbein. He thought Sargent's method was an admirable one in Sargent's hands. If anybody was able enough to follow it, it was a very good one, but it was so difficult a method that a good many of its followers failed to achieve success. He would like to see painters try all the various methods that had produced such fine portraits in the past. They should follow Holbein a little and Titian a little, if possible—the latter was very difficult—and certainly Velasquez if they could. They should try different methods and not keep entirely to one kind of portraiture.

REFRACTORY MATERIALS AND THE WAR.

By Alfred B. Searle, Ph.D.

The successful manner in which the Germans have developed the manufacture of various heat-resisting materials has been clearly demonstrated since the advent of the war, and as time goes on the absence of supplies becomes more and more trying in those industries where heat-resisting materials are required. The manufacture of chemical porcelain, for instance, is almost unknown in Great Britain,* and we have to depend for supplies of this ware on goods which are obtained more or less surreptitiously through neutral countries such as Holland and Scandinavia. The supplies stocked by dealers have never been very large, and these were rapidly depleted. This encouraged a number of British potters to make some simple attempts at the manufacture of refractory porcelain, but most of them soon abandoned it, for though they could make ware which would withstand acid they could not produce a porcelain with the insensitiveness to sudden changes in temperature which is so characteristic of the Saxon ware. Other experiments are being continued, and it is hoped that before long this ware, which is so important to chemists, will be successfully manufactured in this country at prices not markedly higher than have been paid for the imported material. Meanwhile, the use of fused silica ware or "vitreosil" is increasing, as it will meet all the requirements but is more costly than porcelain.

The importation of bricks for building coke ovens and other furnaces from Belgium and other parts of the Continent has necessarily ceased during the war. Firebricks of equal refractoriness can be purchased in this country, but they do not satisfy the tests which the Continental builders of coke ovens consider to be essential. British firebrick manufacturers are making extensive efforts to overcome these objections, and are gradually increasing their ability to make firebricks to fit any reasonable specification. They have much to learn, however, though they have made much more rapid progress since the war began. Firebricks for furnaces and similar purposes where the specifications are less stringent can be made successfully in this country, though the prices of firebricks in extra-European countries before the war were largely in favour of those made in Germany. This was due to the much larger works, organised on an entirely different basis and working on a system of "dumping" which does not appeal to British manufacturers. It is a curious fact that with inferior materials to those commonly used in Great Britain, the Germans have turned out better firebricks and have been able to guarantee results to an extent which British firms have found impracticable. With competition less severe in some respects, British manufacturers are now turning their attention to improving the qualities of their goods, as in the past they have concentrated their minds on the production of cheap bricks. With adequate technical assistance of a kind not generally available they will be able to make great improvements in quality, and should, in time, be able to produce better bricks than any now on the market.

Retorts for the manufacture of coal gas cannot now be imported from Germany, so that gas engineers are compelled to use the home-made products. There is much divergence of opinion as to the relative values of British and German retorts, and it has not been unusual to find German engineers importing British retorts, whilst some British engineers have preferred to purchase German ones. Here again British manufacturers are trying to meet the demands as far as they are able to do so.

The chief difference between British and German refractory materials may be traced to the difference in the ownership and management of the firms. In this country refractory materials are chiefly made by men who have worked themselves up from a small beginning—or the descendants of such men—their chief characteristic being that of a workman whose knowledge and experience have been gained almost entirely in the workshop, and whose theoretical knowledge—either of chemistry, physics, or mechanics—is almost negligible. The German manufacturers of refractory materials, on the contrary, have almost invariably had a sound training in chemistry and engineering; they approach the manufacture from an entirely

* But see the General Note on "Laboratory Ware" on p. 207.—Ed.

different point of view—namely, that of the user turned manufacturer. Consequently they are more impressed with the needs of the user, whilst the British manufacturer is chiefly impressed with the difficulties of manufacture and the limitations imposed by his material. If once this bias could be overcome—and the only remedy is the better education of the manufacturers—there is no question that better refractory goods can be made in Great Britain than can be obtained from the Continent for the same price.

LARGE CONTRACTS FOR ROLLING STOCK IN ITALY.

Some large contracts for rolling stock, probably the largest ever given out at one time, have lately been placed by the Administration of the Italian State Railways in the hands of seventeen different firms, to be made in that country.

The total value of these contracts, including the construction of 5,545 vehicles, of which 5,366 are for ordinary and 179 for reduced gauge, will amount to 56,302,000 lire (£2,252,080 sterling).

The vehicles will consist of 1,385 passenger carriages, 500 luggage vans, and 4,481 trucks and vans for different purposes.

The prices to be paid are as follows:—

		Lire.	£
1st Class Carriages . .	each	54,100	(2,164)
1st and 2nd Class (mixed) .	,,	52,950	(2,118)
2nd Class	,,	52,150	(2,086)
3rd Class	,,	41,450	(1,658)
Luggage Vans	,,	26,700	(1,068)

The prices for vans and trucks vary according to type, viz.: 6,725 lire (£269); 5,125 lire (£205); 10,600 lire (£424); 15,900 lire (£636); 7,080 lire (£283·4).

The narrow-gauge material is chiefly for lines of local interest in Sicily.

GYPSUM DEPOSITS OF THE STATE OF OKLAHOMA.

By Chas. N. Gould, Ph.D.

Gypsum, or sulphate of lime, is widely distributed throughout the western part of the State of Oklahoma. It occurs in rocks of Permian or Upper Carboniferous age, which in this region are known as the Red Beds.

The Red Beds, as exposed in western Oklahoma and the adjacent States of Kansas and Texas, consist of a great mass, several thousand feet thick, of red clay shales. Interstratified with these shales are certain well-defined ledges composed of gypsum.

As found in Oklahoma, gypsum occurs in five separate forms, namely—as rock gypsum; as earth gypsum, or gypsite; as selinite; as satin spar; and as concretionary gypsum. Only the rock gypsum and gypsite have so far been utilised commercially.

By far the most abundant exposures of the material in Oklahoma are in the form of rock gypsum, which material occurs in a number of counties in the western part of the State. This rock gypsum is found in definite ledges, varying in thickness up to 100 ft. The rock is white and massive, and, being harder than adjacent strata, weathers out in the form of conspicuous lines of hills or buttes. The famous "Gypsum Hills" of Oklahoma and Kansas, which are composed of several ledges of rock gypsum, extend north and south for a distance of nearly two hundred miles, and stand out 150 to 200 ft. high above the level plain to the east. This formation is known to the geologist as the Blaine gypsum.

Farther south and west a second line of gypsum hills, not so conspicuous as those just mentioned, extends from west-central Oklahoma to central Texas. This formation, which is known as the Greer gypsum, is made up of five or more separate beds of white massive gypsum, separated by red clays and shales.

Gypsite, or earth gypsum, is usually found in the vicinity of rock gypsum. It is a finely powdered, ashy material, light grey to brown in colour. It is composed of disintegrated rock gypsum, mixed with a certain amount of earthy material.

Gypsum is utilised largely in the manufacture of wall plaster, stucco, plaster of Paris, Keene cement, and other similar products. At various times some fifteen different mills for the manufacture of these products have been erected in the State of Oklahoma. The product manufactured at these mills finds a ready market throughout the southern and western States.

It has been estimated that the amount of rock gypsum available in Oklahoma approximates 123,000,000,000 tons.

THE DEVELOPMENT OF THE CHOCO INTENDENCY.

The Intendency of the Choco is situated in the north-western part of Colombia, between 3° 58′ and 8° 45′ north latitude and 76° 14′ and 77° 51′ west longitude. Its greatest length from north to south, from Punta La Miel to the Calima River, is 350 miles; its greatest width from east to west is 83 miles. The area of the Choco is 18,610 square miles. It comprises the Provinces of Atrato and San Juan. According to the census of March 5th, 1912, the population was 60,544, as compared with 50,185 in 1906. Supreme authority in the Choco is invested in the Intendent, who is appointed by the President of Colombia for two years. The Intendency has no assembly, and the police and other departmental laws are enacted by the assembly of the Department of Cauca (to be distinguished from the Department of Cauca Valley, or El Valle), in which the Choco has no representative. Each of the provinces is governed by a prefect, who is the immediate agent of the Intendent. Quibdo, the capital of the Intendency and of the Province of Atrato, had a population of 15,756 in 1912. It is situated on the eastern bank of the Atrato River, at the point where this stream receives the waters

of the Quito and Cobi Rivers, 270 miles from its outlet into the Gulf of Uraba or Darien.

Only a small percentage of the land is under cultivation, though the soil is of the best alluvial variety and extremely fertile, producing every kind of crop grown in the tropics. Every native family has its small homestead, where enough is grown to supply the family. Agricultural methods are of the simplest variety. Ploughs, harrows, and other modern implements are unknown, such work as these are ordinarily used for being accomplished, if at all, by large knives called "machetes." After the tropical growth is cleared with the machete, corn is scattered broadcast on the surface, or the plantain slips are merely thrust into the ground. The American consular agent at Quibdo says that a large amount of territory is available, and foreigners with perseverance and capital might make a success of agriculture on a large scale. The plantain is probably the article most extensively grown in the Choco, and constitutes with fish and rice the staple food of the country. Estimates place the number of plantain trees in the Choco at 15,000,000. The climate and soil on the lower Atrato are especially suited to rice cultivation, but only about 1,000 acres are planted in rice, most of the supply being imported from the East *vià* Germany.

The number of cacao trees (*Theobroma cacao*) is about 600,000, of which over 400,000 are around Pizarro, 40 miles south-west of Quibdo. The trees are usually 18 to 20 ft. in height with a trunk 8 or 9 ins. in diameter, covered with a cinnamon-coloured bark. The leaves are large and oval. The flowers are reddish, odourless, and usually clustered in groups attached directly to the trunk or the long branches of the tree, where the reddish or brownish oval fruit, 4 or 5 ins. in length, also grows. When the shell of the fruit is opened, 30 to 50 seeds arranged in five vertical rows are found nestled in a bed of pulp. The seeds, about the size and shape of an almond, when dried in the sun turn brown and are ready for market. They are bought at from *5d.* to *10d.* per lb., ground and mixed with sugar and cinnamon. A low-grade chocolate is thus produced, which is consumed in the country. The coco palm, of which there are about 100,000 in the Choco, grows along the coasts, especially around the Gulf of Darien. Vanilla and ipecacuanha trees grow wild in the forests near the mouth of the Atrato. Large quantities of the ipecacuanha root are exported to the United States. A small patch of sugar-cane is cultivated by every family, which also makes its own brown sugar.

The valleys and hills of the Choco are covered with forests, a large part of which consists of trees suitable for lumbering, though many are still unknown commercially. The cedars and "huino," which are very similar, grow in abundance throughout the country. The "canalate," "tuave" and "bosai" are valuable woods, all of a canary-yellow hue, the canalate especially being very hard. The "chonta," a variety of palm about 20 ft. high and 6 or 7 ins. in diameter, is widely used as an exterior surface for houses or made into window-bars. The foundations and framework of buildings are generally built of lignum vitæ. "Mora," from which black dyes are made, and mahogany are both found near the coast. Cedar, huino, mahogany and mora logs are exported to the United States. The Choco is one of the most important districts for the tagua nut or vegetable ivory industry. The tagua palm, 10 or 12 ft. high, grows wild in the forest. Each tree has 6 to 10 clusters containing pods, which break open when ripe, dropping to the ground the nuts and the surrounding pulp. The period required for the clusters to form and ripen is two years, the harvest continuing during the whole year.

The ivory nut district is near the mouth of the Atrato. A virgin forest of tagua has been recently discovered about the head-waters of the Salaqui River, a tributary of the Atrato, in which it is roughly estimated that there are 200,000 trees, which will produce 10,000 to 20,000 tons of ivory nuts. The tagua forests are Government property and are not for sale. The tagua nut when dried has the appearance and texture of dental ivory, and because of the facility with which it can be sawn, carved, dyed and polished, has come to be extensively used as a substitute for the rare and expensive ivory, in the manufacture of buttons, door-knobs, toys and other articles. Probably 8,000 tons of these nuts are exported from the River Leon, which flows into the Gulf of Darien; about 3,000 tons from the River Sucio; 600 tons from the Baudo River district, and 700 tons from Acandi, on the Gulf of Darien. At Cartagena the nuts are re-shipped, mostly to Germany. Although rubber cultivation has only been recently begun, it is estimated that there are 1,500,000 trees in the Choco, by far the largest number of which have been planted. After the metals, rubber is the principal export of the Choco, when prices are favourable. Many species of orchids grow throughout the Choco, and collections reported to be extremely valuable have been sent abroad. There are said to be numerous medicinal plants, from which the natives prepare various ointments.

The gold-mining district of the Choco extends from the junction of the Negua and Atrato Rivers south to the mouth of the San Juan. Almost all the deposits are alluvial. Most of the gold and platinum exported is obtained by native women, working two or three hours a day. They use the antiquated ground-sluicing process as a preliminary to get rid of the coarser gravels, and then with their "bateas" separate the metals from the sand and gravel. The "batea" is a wooden pan, shaped like a very shallow inverted cone, 18 ins. in diameter, and 3 ins. deep at the centre, with two small handles or knobs on the rim. The women handle the bateas with great dexterity, throwing off the gravel and sand by a rotary motion and leaving the gold and platinum dust in the common centre. Another method of mining that is extensively employed by these women is dipping into 3 or 4 ft. of water for the sand and gravel

containing the metals and bringing it up in the bateas. This method is usually more remunerative than the sluicing process.

The gold workings have existed for centuries, but little has been done in the development of the district. The river gravels were being washed by the Indians long before the advent of the Spaniards, and this region furnished much of the gold that was carried back to Spain. In those days the value of platinum was unknown, and when the Indians brought the metal down to the Spanish headquarters in Quibdo the platinum was thrown away. Large finds of this discarded metal have been made recently in Quibdo, and frequently the earth excavated for foundations has yielded sufficient quantities of platinum to pay for putting up the building. The natives were beginning to pan even the streets, thus uncovering large amounts of mud, which was injurious to health. A decree was therefore promulgated in 1913 prohibiting any further washing of earth in the streets of Quibdo. By a law that came into effect in 1910, foreigners are not allowed to denounce or purchase mines in the Choco, but mining property can be leased for a long period. It is expected that within a few years mining on a large scale will be begun. Even under the primitive conditions of the present day the Choco stands second only to Russia as a producer of platinum, and the prospects under improved methods are considered favourable.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Dyers and Dyestuffs.—The differences of opinion disclosed in the reception given to the Government dyestuffs project leave one common ground for regret. From every point of view it is a pity that the scheme submitted was not one to command the adhesion of those who were asked to carry it into effect. The initial scheme being dead, observations upon it are useful only as far as they apply to alternative schemes, and happily its death does not mean that nothing further is to be done to liberate English consumers from dependence upon German suppliers of tar colours. It is well in the first place to realise who are the parties to the direct consumption of dyestuffs. The direct users belong, broadly, to one of two classes—those to whom the cost of dyestuffs is important, and those to whom it is not. Such textile manufacturers as dye their own goods are, in the main, in a large way of business. Colour for dyeing is one of their minor expenses, and the cost of dyeing represents some 1 or 2 per cent. of the total value of the goods. Economy is important in all industrial purchases, but a small addition to the expense of dyeing has a manifestly limited effect upon the total cost of the goods. However, the consumption of colour is not principally in their hands. The great bulk is used by the commission or public dyers, who have just three major expenses, wages, coal, and colour; and to a commission dyer in comparatively a small way a saving of 5 per cent. in dyestuffs translates itself into some hundreds sterling per annum. Rightly or wrongly, the commission dyers have formed the opinions that the present war with Germany will be the last in their time, and that after the war German colours will be not dearer but cheaper than ever. They hold also that for an appreciable period it will cost more to manufacture certain important dyestuffs in England than in Germany. The opinions are given as the prevalent ones, without disrespect to the alternative notion that for a limited time German colours will be dearer after the war, and without regard of their soundness.

Dyers' Competitors.—The commission dyer, in short, insists that he must and will have the cheapest suitable dyestuffs which can be procured —be they German or other. His business is one existing separately from the spinning and weaving of the goods sent to him for treatment, and one capable of being transferred abroad. Not a few Lancashire cottons are sent abroad undyed to be dealt with by Oriental and other craftsmen. The cotton dyer is exposed also to factory competition—for example, from Dutch dyers and calico printers. Not solely for reasons of price, British silks have for years past been sent in small quantity to be dyed black in Lyons and Crefeld. If no large quantity of woven worsteds have been sent abroad in the grey state, it is still true that the advantage of importing undyed rather than dyed cloth has been fully considered in America. Many countries admit undyed at a lower tariff than dyed cloth, in the ostensible interests of the local dyeing industry. While in the cases named the separate interests of the dyer are alone affected, it is sufficiently apparent that the ability to offer shades of a particular degree of fastness is a matter affecting the disposal of orders for weaving as well as for dyeing. Indubitably, in some circumstances, to put obstacles in the way of the English dyer is to promote the export of undyed, unfinished, and unwoven goods at the expense of business in the completed article.

Cheap Colours.—The interest of the textile public in the matter of dyewares is that of the consumer, and not that of the colour manufacturer. It follows that any solution of the difficulty involving a general rise in prices must encounter commercial as well as political opposition. British consumers might be said hitherto to have been spoiled, for they have obtained German colours at prices only rendered possible by the significant provision in the general terms of sale forbidding the re-export of the dyestuff from the United Kingdom. Although it has been argued with plausibility that the best security for low prices in the future lay in the investment of capital in colour-making at home, consumers have not shown readiness to act upon so long a view.

Indeed, numbers of consumers have no capital to spare—a proportion of them are, in effect, financed by their colour suppliers and coal merchants. It may be some satisfaction to feel that the breakdown of the Government scheme is due to no fears of the ultimate possibility of establishing a strong British colour industry, and that the rock on which it has foundered is the old one of commercial consideration. The rock is not an easy one to avoid, and it is possible that the navigators paid too little heed to it. While they talked of the larger and more distant prospects, those to whom they spoke thought consistently of the immediate. Had there been nothing more required than the change over from the choice of suppliers to dependence upon a central dyestuff manufacturing organisation, it is certain that some effort would be necessary to make that change agreeable.

Conditions in Germany.—It has been somewhat indefinitely reported for some time that little or no work was being done in the German colour factories. The information is confirmed by a petition, apparently framed in November by the Verein der Deutschen Textilveredlungs-Industrie. The Government was asked especially to facilitate the import of dyewoods and tanning materials, and to restrict the export of chemical colours to neutral countries "so long as German requirements have not been fully covered." It would be instructive to know how much of this inability to cope with domestic needs arises from the cessation of supplies of raw products from England. The other portions of this petition are suggestive, notably the request for "credit facilities in the important branches of the weaving industry," and for aid in importing materials and exporting goods similar to that given to other industries. The Government was asked not to adopt any further measures injurious to the Kartels, and pressed to take steps to moderate the price of living, "because such increase is the principal cause of the contraction of the demand for woven goods." With external trade at a minimum, internal trade in a bad state, prices high for cotton and wool, and an insufficiency of dyewares, the German textile industries can by no means be in a prosperous condition. Approximately, one half of German production lost its markets when the seas were closed against German commerce. As the other half is restricted at both ends it may not be long before work is limited to one or two days a week, and the indefinite continuance of so disastrous a state can be contemplated with no satisfaction in any German circles.

Simplicity and Inventions.—When electricity was newer as a motive force it was regarded with distrust as a power altogether more intangible and incalculable than the steam to which manufacturers were well accustomed. Familiarity has largely removed these fears, without, however, leading to the extensive use of current except for light and power. In a paper before the British Association of Managers of Textile Works, Mr. Frank Nasmith, of Manchester, detailed a number of directions in which electricity has at least some promise of wider use. Pneumatic and electrical forces were considered together, and, of the two, compressed air is the less familiar in general mill practice. The conditions do not obtain in the mill which have made pneumatic transmission widespread in mines and shipyards. The textile manufacturer, except in rare cases, is not a trained engineer, and has not a professional engineer's outlook upon mechanical problems at large. It is to be believed that some managers and employers have not yet overcome prejudices against compressed air resembling those which at an earlier date militated against the use of electricity. Doubtless some objections to air trunks, pipes, and projections are traceable to the overcrowded state of rooms, and others are known in practice to have arisen from an unwieldiness of apparatus incommensurate with the benefits conferred by its use. Doubtless in minimising inconveniences and simplifying his apparatus the engineer is taking the shortest cut to the favour of the manufacturer. Properly enough, the manufacturer is exhorted to keep abreast of science. If he spoke his mind frankly, the manufacturer would probably beg the scientific engineer to reduce his inventions to the lowest and simplest terms. Mr. Nasmith, in dealing with the possible extensions of the use of the newer forces, expressly assumed that any improvements adopted would reduce the manual operations required. The condition is the precedent to their adoption, and it may be urged strongly upon inventors that simplicity is the thing that manufacturers are really seeking.

NOTES ON BOOKS.

Optic Projection. By Professor Simon Henry Gage and Henry Phelps Gage. Ithaca, New York: The Comstock Publishing Company. 1914.

In January, 1911,* Mr. S. H. Gage, Emeritus Professor of Histology and Embryology at Cornell University, contributed to the *Journal* of the Society an interesting article on the origin of the photographic lantern-slide, in which he was able to show conclusively that the earliest application of photography to the projection lantern was made in America. In 1850 transparent positives for use in the lantern were made and advertised by the Brothers Langenheim, who were, according to Professor Gage, the owners of Fox Talbot's American patents. The albumen dry-plate process was the one employed, the use of collodion for photographic purposes not having been discovered

* *Journal*, Vol. LIX. p. 255. See also p. 292 for some further comments on the subject by the Secretary of the Society.

until 1851, when, as is well known, Archer first published an account of his invention.

This article was the outcome of the researches which were being made by Professor Gage, with a view to the publication of the book which has now appeared, "Optic (or, as we on this side of the Atlantic would call it, 'Optical') Projection."

The authors, however, state that although it was their intention when the work was undertaken to include an extended account of the discoveries and inventions relating to vision, this idea was abandoned because the present work had already exceeded its limit in size. The historical matter is therefore reserved for a future work. That it may not be very long before Messrs. Gage undertake the production of such a book is certainly to be hoped, because it would probably be of a greater general interest to students of the subject than the present volume, complete as this appears to be in its own line.

The volume under review is an elaborate and apparently exhaustive account of apparatus used for projection, with all the various artificial lights and also with sunlight, together with all supplementary and kindred apparatus. For instance, the projection microscope is fully described, and there is an elaborate chapter devoted to the cinematograph. The different sources of illumination are fully dealt with; the electric current at considerable length. There is also a chapter on the preparation, use, and preservation of lantern-slides; another chapter on drawing and photography with projection apparatus, and yet another on the projection of images of opaque objects.

The optical principles involved are treated at sufficient length, and indeed there seems little information that an operator can require which he would not find in this book. It is very elaborately illustrated, and is full of detailed instructions for the use of all the appliances described. It should be added that although history has been relegated to a future volume, there is a brief historical summary, and a fairly full bibliography.

GENERAL NOTES.

EGGS IN SHANTUNG.—Shantung is one of the leading egg-producing provinces of China. Chickens are for the most part hatched by a native process of incubation, consisting in placing eggs in earthenware jars, which are set upon kongs or beds built of brick and clay, and within which slow fires, generally of coke or charcoal, are kept burning. The eggs are carefully turned from time to time. The kongs used are generally those which serve the family for beds, each family throughout the country districts rearing a number of chickens in this way. There are no large concerns engaged in this business in the sense that obtains in the poultry industry in this country. Old women, it is said, sometimes carry a number of eggs strapped about their waists, under their outer garments, for incubating purposes. About two weeks after the chickens are hatched they are taken to the market and sold, the family keeping a sufficient number for domestic purposes. The production of chickens and eggs in Shantung is not a business in which anyone engages to the exclusion of other work. The millions of eggs which are produced daily in the province are the collections of a dozen or less from each of the numerous households contributing to the general supply.

VINTAGE IN FRANCE, 1914.—The *Journal Officiel* gives the following statistics respecting last year's vintage in France, which, notwithstanding the war and the occupation of five departments by the Germans, appears to have been most abundant. Those departments from which no returns were available are the Aisne, Ardenne, Meurthe, Moselle, and the Oise.

	1913.		
	Hectolitres.		Gallons.
Stocks	3,791,599	..	83,421,778
Production . .	41,053,832	..	903,184,304
	44,845,431	..	986,606,082
	1914.		
	Hectolitres.		Gallons.
Stocks	5,719,546	..	125,830,012
Production . .	51,134,159	..	1,124,951,498
	56,853,705	..	1,250,781,510

This shows an increase of 10,080,327 hectolitres (221,767,194 gallons) in favour of last year's vintage.

INSTITUTION OF PETROLEUM TECHNOLOGISTS.—Lord Fisher, of Kilverstone, and Vice-Admiral Sir Edmond J. W. Slade have been elected honorary members of the Institution of Petroleum Technologists.

INOCULATION AGAINST TYPHOID.—Sir Frederick Treves, speaking at a meeting held in the Society's Great Room on Friday, January 22nd, under the auspices of the Chadwick Trust, said that the proof of the value of the protection afforded by inoculation, as demonstrated by the results in the present Expeditionary Force, was unquestionable. Since the war began there had been in the British Expeditionary Forces—and these figures were astonishing—only 212 cases of typhoid fever, and of these 201 were not protected men. Of these 201, 173 had not been inoculated at all; 28 had received one inoculation, or had not been inoculated for a period of over two years. Of the 212 men there were only 11 men who had been inoculated. These figures could not be gainsaid. Moreover, among these 212 men there had been 22 deaths, and all these deaths had been non-inoculated men, and not a single man had died of typhoid fever in the British Expeditionary Force

who had been inoculated. There the matter ended, and those who attempted to persuade the soldier not to be inoculated played into the hands of the enemy, and gave him exactly the advice the Germans would be only too pleased to give him. Since the delivery of his address Sir F. Treves has obtained later official figures, which he published in a letter in the *Times* of January 26th. They are as follows: Of the first 421 cases of typhoid fever in the present campaign among British troops, 305 were of men who were not inoculated. In the 421 cases there had been 35 deaths. Of these deaths 34 were men who had not been inoculated within two years. Only one death occurred among patients who were inoculated, and that man had only been inoculated once. Sir Frederick pertinently adds: "In view of this evidence, and in view of the grievous injury inflicted upon our gallant troops by those who—in widely disseminated leaflets—advise the soldier against inoculation, one wonders if the Defence of the Realm Act is not sufficiently powerful to put a stop to this heartless crusade and this direct playing into the hands of the enemy."

LABORATORY WARE.—Messrs. A. Gallenkamp & Co., Ltd., announce that a manufacturer in Staffordshire has succeeded in making some porcelain which compares favourably with the porcelain ware for laboratory purposes (such as evaporating basins, crucibles, beakers, etc.) which, up to the beginning of the war, was only obtainable from Germany. The new ware has been tested at the County Pottery Laboratory, Stoke-on-Trent, and pronounced to be as satisfactory as the German. It can also be supplied at prices not much higher than those of the German ware before the war. An association, to be known as the British Laboratory Ware Association, is about to be formed, whose object will be to stimulate the production in this country of a large number of laboratory requisites hitherto only produced in Germany. It was felt that combination of this sort was necessary in order to make it worth while for manufacturers to go to the expense of putting down additional or new plant. It is also stated that the problem of manufacturing a suitable quality of glass beakers and flasks has been solved, and certain sizes are now being made for trial orders.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock (except where otherwise announced):—

FEBRUARY 3.—OCTAVIUS CHARLES BEALE, Past President of the Australian Manufacturers' Association, "Imperial Industrial Development after the War." GEORGE R. PARKIN, C.M.G., LL.D., D.C.L., Organising Secretary of the Rhodes Scholarship Trust, will preside.

FEBRUARY 10.—F. VINCENT BROOKS, "British Lithography in 1915."

FEBRUARY 17.—ARTHUR WILCOCK, "Decorative Textiles, and the Designer's Relation to the Industry." SIR CHARLES WALDSTEIN, Litt.D., Ph.D., will preside.

FEBRUARY 24.—W. J. ASHLEY, M.A., M.Com., Ph.D., Professor of Commerce in the University of Birmingham, "The Economics of the War." The RIGHT HON. SIR GEORGE HOUSTON REID, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, will preside.

MARCH 3, at 4.30 p.m.—WILLIAM POEL, "Shakespeare's Profession."

MARCH 10.—J. W. GORDON, "Patent Law Reform and the War."

MARCH 17.—H. M. THORNTON, "The Industrial Uses of Coal Gas."

MARCH 24, at 4.30 p.m. LADY LUGARD, "The Work of the War Refugees' Committee."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 11.—CAPTAIN SIR GEORGE DUFF DUNBAR, Bt., I.A., "Tribes of the Brahmaputra Valley." LIEUT.-COLONEL SIR FRANCIS YOUNGHUSBAND, K.C.I.E., LL.D., D.Sc., will preside.

MARCH 18.—LIEUT.-COLONEL A. C. YATE, I.A. (retired), "The Indian Army."

APRIL 15.—M. M. S. GUBBAY, I.C.S., "Indian Trade and the War."

MAY 13.—PERCEVAL LANDON, "Basra and the Shatt-ul-Arab."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

FEBRUARY 2.—EDWARD R. DAVSON, "Sugar and the War." LORD DESBOROUGH, K.C.V.O., will preside.

MAY 4.—S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced:—

THOMAS WORTHINGTON, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. THORNE BAKER, "The Industrial Uses of Radium."

FRANK BAINES, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. HULME, "Patent Law."

D. Y. CAMERON, A.R.A., R.E., "Etching."

ROGER FRY, "Post Impressionism in Design."

C. H. SHERRILL, "Ancient Stained Glass."

A. S. E. ACKERMANN, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

AUGUSTUS VERNON HARCOURT, D.C.L., LL.D., D.Sc., F.R.S., "On an Economical and Smokeless Grate, and on the Measurement of the Efficiency of Open Grates."

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

May 13.

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

March 30.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

F. MOLLWO PERKIN, Ph.D., F.I.C., F.C.S., M.Inst.P.Tech., "Oils, their Production and Manufacture." Three Lectures.

Syllabus.

LECTURE III. FEBRUARY 1. Vegetable oils Raw materials Sources of supply Methods of manufacture—Methods of refining—Edible oils—Paint oils.

M. H. BAILLIE SCOTT, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evenings, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

February 15, 22, March 1.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. F. Mollwo Perkin, "Oils, their Production and Manufacture." (Lecture III.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Professor E. W. MacBride, "The Present Position of the Theory of Organic Evolution."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Presidential Address by Mr. N. Scorgie.

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. Exhibition of specimens of Chemicals and Apparatus hitherto produced abroad and now being manufactured in this country.

TUESDAY, FEBRUARY 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. E. R. Davson, "Sugar and the War."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Muscle in the Service of Nerve." (Lecture III.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Mr. H. Raeburn, "In the Caucasus 1914."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. B. C. Wickison, "Effect, its Value in Pictorial Photography."

Rontgen Society, Middlesex Hospital, W., 8.15 p.m. Dr. S. Russ, "Measurements of the Radiations from the Coolidge and other X Ray Tubes in Clinical Practice."

WEDNESDAY, FEBRUARY 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. O. C. Beale, "Imperial Industrial Development after the War."

Civil Engineers of Ireland, Institution of, 35, Dawson-street, Dublin, 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Annual Meeting 2. Mr. G. D. Elsdon, "Note on the Determination of Sulphates in Flour." 3. Dr. W. R. Schoeller, "General principles governing the complete analysis of Minerals and Ores."

Entomological Society, 11, Chandos-street, W., 8 p.m.

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. A. Vallance, "Reims Cathedral."

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. A. H. Mackinney, "Problems of Modern Illumination."

THURSDAY, FEBRUARY 4...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Dr. Marie Stopes, "A new, well petrified fossil Wood or Bark—Angiosperm or Gymnosperm?" 2. Dr. H. Drinkwater, "Brachydactyly as an example of Mendelian Inheritance."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Mr. S. U. Pickering, "Metallo compounds of cobalt and nickel." 2. Mr. J. N. Rakshit, "Preparation of dinitro-dichloro methane by simultaneous nitration and chlorination of acetone." 3. Mr. M. O. Forster, "Azotisation by chloroamine."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. G. Plimmer, "Modern Theories and Methods in Medicine." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. S. Greenslade, "Eighteenth Century English Table Glass."

University of London, University College, Gower-street, W.C., 5.30 p.m. Monsieur C. Pompeye, "Belgian Art." (Lecture III.)

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Discussion on report on "A Standard Specification for Reinforced Concrete."

FRIDAY, FEBRUARY 5...Royal Institution, Albemarle-street, W., 9 p.m. Professor A. W. Crossley, "Science and Industrial Problems."

Geologists' Association, University College, W.C., 8 p.m.

SATURDAY, FEBRUARY 6...Royal Institution, Albemarle-street, W., 3 p.m. Dr. H. W. Davies, "Music To Untrained Listeners." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,246. VOL. LXIII.

FRIDAY, FEBRUARY 5, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, FEBRUARY 10th, 8 p.m. (Ordinary Meeting.) F. VINCENT BROOKS, "British Lithography in 1915." CARMICHAEL THOMAS, Chairman of the *Graphic* and *Daily Graphic*, will preside.

THURSDAY, FEBRUARY 11th, 4.30 p.m. (Indian Section.) CAPTAIN SIR GEORGE DUFF DUNBAR, Bt., I.A., "Tribes of the Brahmaputra Valley." LIEUT.-COLONEL SIR FRANCIS YOUNGHUSBAND, K.C.I.E., LL.D., D.Sc., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, February 1st, DR. F. MOLLWO PERKIN, F.I.C., F.C.S., delivered the third and final lecture of his course on "Oils, their Production and Manufacture."

On the motion of the Chairman, PROFESSOR VIVIAN B. LEWES, a cordial vote of thanks was passed to Dr. Perkin for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, February 2nd; LORD DESBOROUGH, K.C.V.O., and subsequently COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, in the chair. A paper on "Sugar and the War" was read by MR. EDWARD R. DAVSON.

The paper and discussion will be published in a subsequent number of the *Journal.*

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, January 26th, 1915; SIR OWEN PHILIPPS, K.C.M.G., in the chair.

THE SECRETARY of the Section said Lord Kitchener had informed the Society that he would have been very pleased indeed to attend the meeting had the times been normal, and that he took special interest in the two countries under discussion in the paper, but he was sure that the Council would appreciate his inability to find the time to be present.

THE CHAIRMAN said he felt very much honoured at being invited to preside that afternoon. He was quite sure that Major Leggett required no introduction; he was an old member of the Society and had spoken at the Society's meetings on more than one occasion. The territories of British East Africa and Uganda would always awaken deep interest among British people from their geographical setting, their romantic history, the extraordinary rapidity of their growth and progress, and their vast possibilities for future development. No one was better able than Major Leggett to speak on those things. Many names would always be coupled with East Africa and Uganda, and not the least the names of Lord Kitchener and Sir Frederick Lugard; and in future when men looked back on the commercial developments of those countries he thought Major Leggett's name would be remembered with honour.

The paper read was—

THE ECONOMIC DEVELOPMENT OF BRITISH EAST AFRICA AND UGANDA.

By MAJOR E. H. M. LEGGETT, R.E., D.S.O.,
Managing Director of the British East Africa Corporation.

When the Council of this Society did me the honour of asking me to read a paper upon East Africa, I asked leave to couple the two Protectorates, British East Africa and Uganda, and by thus mentioning them separately at the

outset to make it plain that, in the inventory and the Blue books of the British Empire, there appear two names, two countries, and two sets of problems. From that starting point I hope to show you these two great areas are complementary one to the other, each supplying something that the other lacks, so that the course of their development, in part due to organised effort and in part almost automatic, tends more and more to dependence upon a centralised programme. And, lastly, I would hope to indicate something of what I believe to be the inevitable influence of these areas, as governing the economic future of something like one-third of tropical Africa, this power following from the fact that the port of Mombasa is the gateway of the shortest road to the great African system of inland waterways--Lake Victoria, Lake Chioga, Lake Albert, and the head-waters of the Nile.

It may surprise you to hear that the economic history of these countries, in the sense which we are discussing to-day, began barely a dozen years ago. Yet that is literally the fact, and indeed overstates it. It is certainly true that when Great Britain rather reluctantly assumed the pride of adding these areas to the list of countries that it was protecting—and paying for—there was no clear idea how they were to recompense her for her anxieties of governance and expenditure.

It is probably fair to say that England went in with three objects: one business object, viz., to keep someone else out from the head-waters of the Nile; and two objects moral, to destroy the slave trade and to protect the missionaries. The business object, that of occupying a remote and difficult country at great expense to keep Germany out, would be economically sound as an item in the Imperial balance-sheet, but was not expected to be revenue-earning in itself. The other two objects are among those for which the reward is not expected to be of the material order.

A brief historical summary is essential to an understanding how development received its first impulse, and how certain factors came on the scene almost accidentally, but which will probably have a permanent influence on the politico-economic future of East Africa and Uganda. The glimmer of the future came to Sir Samuel Baker, the first European to reach Uganda and Lake Albert. On his return in 1867, from nearly two years spent in what is now the Northern Province of Uganda, he wrote of the fertility of the soil, and the industry of the natives, and he sketched, almost as a dream, the advantages to England if it were only possible, as he doubted how it ever could be, to bring those areas and peoples into communication with the civilised world, to transport their cotton and grain raised by their free labour to the workshops and markets of Europe, and to send them in return the products of the home countries. Baker's trip had been made under the nominal protection and ægis of the Khedive of Egypt, Tewfik Pasha, whose character was so remarkable a combination of the gambler and the statesman. Baker returned to Equatorial Africa in 1869 as the Khedive's Governor-General, and in the same year an Egyptian expedition of troops and warships arrived at Kismayu on the East Africa coast, but only to find a British squadron from the East India station had arrived a few days previously, and the Egyptians returned home. A glance at the map shows the breadth of Tewfik's conception. But this incursion into the territories of the Arab Sultan of Zanzibar was upsetting to the mind of that potentate. His territory ran from Muscat on the Persian Gulf as far south as Cape Delgado, and in his island headquarters he grew rich from the spoils of trading expeditions which penetrated far into the interior of the mainland, bringing back slaves and ivory. The coast-line was one continuous cocoanut plantation, worked by slave labour. It would certainly not suit His Highness to have his chief customer in the slave traffic, the Khedive of Egypt, establishing himself, in the same line of business, in the middle of his own territory. So Sultan Bargash of Zanzibar offered in 1877 to his friend, Sir William Mackinnon, a seventy years' lease of the Zanzibar dominions on the mainland; but our Foreign Office foresaw trouble, and the matter was not then proceeded with. The time was that of the Dual Control in Egypt, when relations between France and England were going through a period of strain that could not have been displeasing to Prince Bismarck. The events of 1882 in Cairo were quickly followed by great activity on the part of Germany in acquiring concessions along the east coast of Africa, and in 1886 England realised the situation sufficiently to step in and peg out a claim in the shape of Mombasa and its hinterland. The boundaries of the Sultan of Zanzibar's dominions were investigated by none other than Captain (now Lord) Kitchener. His next visit to that region was in 1911, on a private holiday trip, and the greeting given him then by old Arab friends of

twenty-five years before was eloquent of the memories his first visit had left behind him.

To resume. This definition of areas led the Foreign Office at last to recognise Sir William Mackinnon's lease, and to confirm it as a Royal Charter granted to Mackinnon's Company, "The Imperial B.E.A. Co.," in 1888. It illustrates the various methods of Empire-building that meantime Germany had secured her 400-mile strip of coast and its hinterland, since called German East Africa, by some pressure and a payment of £120,000 to the Sultan of Zanzibar, displacing all the officials of the latter, and establishing a rigid rule, while England preferred to lease its sphere, maintaining the flag of the Sultan and his officers to administer all Arab questions, and imported Indian officials, whose tradition is to lead rather than to order, and to leave native laws and customs as far as possible undisturbed.

So far the coast. But Emin Pasha, a German subject in Egyptian employ, had by some influence succeeded as Egyptian Governor of Equatorial Africa some years before. He became lost, and in 1889 a German official, Karl Peters, set out to find him. He started from Lamu on the coast, where many German concessions had been secured from Arab chiefs, and the semi-independent Sultan of Witu, and the search party soon displayed itself as a fully equipped expedition, and proceeded to run a ring round the small British sphere of influence. It penetrated to the Lake region, and made territorial treaties with everyone who could claim to be a chief. To the everlasting credit of Great Britain and himself, Mr. (now Sir F.) Jackson, the present Governor of Uganda, who was exploring the interior of East Africa with an Imperial B.E.A. Co.'s party—but actually with, I believe, orders not to go as far as Uganda—heard of Peter's activities, and raced him, keeping the intruder at arm's-length but pushing him gradually away by the polo manœuvre of "riding him off," and thus enabled our Government to deny the German claim of the latter's effective occupation of the territory at the sources of the Nile. Egypt was quiet, and its future beginning to take shape, the French were busy in Algiers and the Sahara, and the British Government began to realise the escape it had had. Captain (now Sir Frederick) Lugard was sent to Uganda to establish the authority of the Imperial Company, for even yet the Imperial Government was reluctant to assume expense and direct responsibility. How Sir Frederick and Captain Williams held on and paid the troops themselves, after being ordered to withdraw, is another instance of taking the chances of success for the flag versus censure of the individual. In 1894 the British Government bought out the Imperial Company, and it is no coincidence that in 1895 Lord Kitchener's patient advance began for the recovery of the Sudan. By 1898 the Uganda Railway was commenced, to reach from Mombasa to Lake Victoria, and in that year Lord Kitchener fought the battle of Omdurman. Thus was the scheme of Tewfik realised, but not by Tewfik. Had he succeeded, who can doubt but that the Mahdi of the Sudan, the bloodthirsty King of Uganda, and the slave-raiding Arabs of the East African coast, would have merely been replaced by an authority as overbearing, as wasteful and eventually as weak, the prey to intrigue, and carrying the germs of decay? What has England done with this heritage?

Strictly following the principles in vogue in those days, the British Government, on assuming the protectorate of a portion of the mainland strip of the Sultan's dominions and its hinterland, handed over the territories to the Foreign Office, which kept a watch upon foreign activities, consummated treaties with ruling chiefs, protected generally, but eschewed anything like active administration. The area around the head-waters of the Nile, which we now call Uganda, was in military occupation, and connected with the coast by an expensive caravan journey of some 800 miles. The coast was looked after by the Foreign Office Consul-General at Zanzibar. The 800 miles between the two areas were unadministered outside of rifle range from the posts along the caravan road, and the passage of each convoy across the Great Rift Valley, the cattle grounds of the warlike Masai tribe, was generally an adventurous proceeding. Exports from the interior consisted solely of ivory, and the Arab slave-worked plantations on the coast yielded some copra and grain. Imports consisted mainly of groceries for the white officials, cotton cloth, and beads, and a great quantity of telegraph wire, mostly to replace the miles of the same article regularly cut down by the natives to be beaten out into spear-heads or bracelets.

But the genius of Lord Salisbury, and his study of what he, at that time, was calling large scale maps, committed England to a great piece of constructive development. The Uganda Railway will rank in the history of Empire building with Lord Strathcona's Canadian Pacific line, and Cecil Rhodes's Cape to Cairo projects.

Many reasons have been given why the Uganda Railway scheme was embarked upon. The original estimate was about 2½ millions sterling, and it was argued in the House of Commons on strict business lines. England had committed herself, at the Brussels Convention of 1890, to put down the slave trade in East Africa. To do this, the problem, like the income tax, must be tackled at the source. Hence the expensive occupation of Uganda. Leakages must be safeguarded by a naval squadron on the coast. These items cost us £250,000 a year. Hence the interest charges on 2½ millions for a railway that would destroy the slave trade at its source, and save the naval squadron, would show a saving, that is to say, an Imperial profit. The working expenses of the line were reckoned at about £40,000 per annum, and the revenue at £22,000, to be derived from carrying Government stores to Uganda at £12 per ton against £80—the caravan rate. A small revenue was expected from ivory traffic and trade goods, but a working loss was anticipated of about £18,000 per annum, certainly not much to knock off the Imperial economies that were hoped for. Beyond this, no economic results were predicted.

To some of us it may seem doubtful if the financial argument for the railway thus modestly, as it now appears, dangled before the business men of the House of Commons, was really the motif of the project. Let us look outside and see. The Uganda Railway was first mooted about 1894, when Lord Kitchener's advance on Dongola was beginning, and took definite shape in 1896, contemporaneously with the building of the desert railway towards Khartum. In 1898, when the Mahdi was smashed, the Uganda Railway scheme bounded ahead, and it began to be suggested that it might form a valuable alternative means of military access to the head-waters of the Nile should the Egyptian route be at any time closed. The unfriendliness of some of the European Powers, and especially of Germany, during the South African War, along with the not unconnected trouble in China in the year 1901, coincided with an expediting of Railway construction work in East Africa so insistent that the originally projected terminus at the deep water of Port Victoria, at the north-east corner of Lake Victoria, was abandoned in favour of the present terminus at Kisumu. This saved eighty miles of length, at least a year in time, something in money, but all to the great economic disadvantage of the railway and lake steamer traffic for many a long year—indeed, until the original line to Port Victoria is built. But the line reached the Lake in 1902, and quick communication by rail and water, from the coast to Uganda and the Nile, was an accomplished fact.

I will not stop to describe the work of construction of this line, 584 miles in length, which crosses two great mountain chains, the one over 7,000 and the other over 8,000 feet above sea-level, dives down the steep escarpments into the Great Rift Valley between them, skirts lakes well known to every schoolboy since Rider Haggard wrote his "Alan Quartermain," and traverses Nature's greatest Zoological Gardens, the lands of the blood-drinking Masai and the garment-scorning Kavirondo. Enough to say that the cost was over 5½ millions instead of the 2½ millions estimated, and that the difficulties of construction were such as to disturb the temper of even a Foreign Office official. The carriers died like flies; mules, camels, rope-haulage ways, and every other means of transport for materials were requisitioned from the Foreign Office construction committee at home. But the last straw was reached when the engineers demanded transport elephants from India. The reply of a distinguished official of Whitehall, which is not to be found in the Blue books, is said to have been, "Tell them to go and catch the animals themselves."

Meantime the Foreign Office had divided the country into two, the Rift Valley and warlike Masai forming a natural dividing line. From the coast to the Rift became the British East Africa Protectorate, thence to Lake Victoria and beyond to the Nile and the Congo border became the Uganda Protectorate. A Foreign Office Commissioner was put in charge of each territory, and something like administration began to emerge. Railway construction had brought a vast army of British Indians into the country, who followed the railway line and soon proved to the natives that skins and hides had a value in excess of their usefulness for making assegai shields, and that many captivating articles could be acquired by the natives, and especially by their wives, by the simple process of selling something they produced and did not value for something they coveted more. Railway transit made this natural development inevitable. Still, however, it is true to say that little if anything was done by the ruling authorities to stimulate this desirable process.

Some groping about the future there certainly was. The possibilities of white settlement were borne in upon Sir Charles Eliot, who sent an

informal commission to South Africa in 1902 3 to invite colonists to take up land. But it may be surmised that his idea was rather to create for political and military purposes a resident white garrison, of the type that prefers a detached existence, not necessarily lucrative so long as it enjoys the sense of land-ownership and cannot see its neighbours' smoke, rather than the more ambitious modern type, who in making money for himself makes revenue for the State. But the home policy towards the natives had not been defined. Sir Charles and the Foreign Office disagreed in public, and the former resigned. The influx of Europeans, however, continued, though the Home Government seemed to be in two minds as to whether it wanted them or not. Sir Charles Eliot was succeeded by Sir Donald Stewart, who frankly advocated the colonial ideal, and more Europeans arrived.

In April 1905, the Protectorates were transferred at home from the Foreign Office to the Colonial Office. Incidentally, Lake Victoria became the boundary between British East Africa and Uganda. The period of military occupation, of treaty making, and of economic stagnation came to an end, and the period of business began. Hopes ran high, for the Colonial Office under Mr. Alfred Lyttelton had succeeded to the traditions of Mr. Chamberlain, who had not been afraid to say that England must develop her Imperial estates.

Speaking in round figures, this is the position to which the Colonial Office succeeded. The Imperial Government had waived its right to debit interest upon the £5½ million railway. This was a fine endowment, but in any case the Protectorates could not have paid it, for, to make ends meet on the ordinary running of the countries, grants-in-aid of about £200,000 to British East Africa and £150,000 to Uganda were being contributed by the Imperial Treasury. Local revenues were trifling. About £100,000 was coming in from the native hut tax, there was something from Customs duties, and the Uganda Railway accounts were showing a profit of about £40,000 per annum, which was transferred to the credit of the British East Africa treasury. This railway profit was in part made by charging each Government department for the carriage of its materials and officials. This system is sound for accountancy purposes, but it was rather stretched when granting to certain higher officials the privilege of a reserved compartment, and then charging the departmental votes with the value of four rail fares. This hurt nobody in British East Africa, and merely created more imposing figures in the debit and credit side of the Protectorate accounts, which conveyed the idea of increasing prosperity to people at a distance. Uganda had not the same consolation, for her payments to the Uganda Railway went into the British East Africa treasury and reduced the amount that Uganda could spend on her own development. This rather anomalous state of affairs still continues.

A year later, in 1906, I visited British East Africa, German East Africa, and Uganda, on the suggestion of the then Secretary of State, Mr. Lyttelton, who asked me to get him information as to commercial and agricultural possibilities. I well recall his words: "I want traffic for the railway—something that the world wants and which shall be a staple, reliable, and increasing traffic." I can imagine our Chairman of to-day expressing the same wants for his ships that serve the East African coast.

What I found in 1906 was briefly this. The white settlers were unshakable in their belief in the land, an optimism in itself a glorious asset, for it was to see them through the hard period of try and try again. They were trying, among other things, coffee, wheat, maize, potatoes, fruit, wattle, cattle, sheep, ostriches, sisal hemp, ramie fibre, beans, cotton, tobacco, cocoanuts and rubber. Lord Delamere then, as now, stood out as the leader, afraid to tackle nothing that seemed worthy of experiment, and putting his results freely at the service of his fellow colonists. Captain Grogan investigated the forest resources of the country. An American syndicate spent a large sum in trying to extract fibre at a profit from the wild sansevieria.

In all this activity one could see the settlers' intention to create a State, something of a combination of the plantation dependency, such as Ceylon and Malaysia, and the purely colonial dominion, such as Australia and South Africa. German East Africa, which lay next door, and which had ten years' start of the British areas, owing to the German methods of forcing the pace and of free expenditure of State funds, was being developed along lines that frankly regarded the white man's output as everything, and the native as the mere raw material of labour. But there were a few in East Africa and Uganda who believed that the real gold was there, in the shape of a native population, which, take it all round, was not averse from being influenced to produce exportable commodities so long as it could do so, at any rate to begin with, in the ways it had always understood.

Some of the missionaries in Uganda, and some officials in both Protectorates, had tried the experiment of giving out cotton seed to the natives, to grow on their own lands and with their own free labour, promising them a market for the crop. This had by 1906 resulted in a harvest of some 200 bales in Uganda, worth perhaps £2,000, bought by Europeans and Indians. The proceeds were eagerly spent by the natives in buying cotton cloth and other imported goods. Mr. Ainsworth, one of the senior Provincial Commissioners of East Africa, had begun to give out seed potatoes, beans, and other seeds to the British East Africa tribes, with advice how to sow and how to reap. The Indian traders, already mentioned as spread over the land by the building of the railway, lost no time in educating the natives in the practice of selling and buying. The theory of the dignity of labour, so cold a creed in itself, became warmed by what Mr. Gordon Selfridge calls the "instinct of merchandising," which exists somewhere in the composition of most human beings. Still there was no official programme, at least none made public to the settlers and traders. One may assume that the policy of Downing Street was to give every tendency a fair run, and to trust to the genius of Englishmen in the bulk to bring out the best. The mountains were not going to labour to bring forth a possible mouse, but should a goodly offspring of the lesser hills see the light, the mountains were prepared to do fairy godmother in due proportion—or so we all hoped.

But there were three essentials that could not be left to evolve themselves, and these three are all matters of communications. The railway, a broad street from end to end of the country, had been provided at huge cost. But of side streets—that is to say, country roads—there were none; harbour facilities were equally nil; and the link with the world's markets, ocean shipping, was practically wholly foreign. I found in 1906 that though Mombasa had a sailing once a month by each of four steamship lines, one German, one Austrian, one French, and one English, the last was only a coasting boat running as far as Aden, and 93 per cent. of the exports to Europe were carried in foreign bottoms, and more than half of this in the German ships. As developments in East Africa and Uganda proceeded and succeeded, this state of affairs became one which I ventured to describe in this room at the time as being something that no Englishman in those countries could see without grave misgiving, and even a loss of self-respect. Individual Britishers were hammering out the future of the country upon the anvil of their pride in work done, but they could not provide the money for the roads. Nor were they allowed to build the harbour with private capital. And they could not put up the funds needed to make good the actual cost of keeping up a British shipping service to carry the small exports of those days. So the produce had to travel mainly by the German boats, subsidised by the German Government, and fell unavoidably under powerful influences that sought to divert these raw products of British energy to the people and the workshops of Germany. From this followed automatically the shipment of German goods in exchange, until, by the year 1911–12, the tide was setting fast between Hamburg and Mombasa. Half the population of Mombasa, the ocean port of the two Protectorates, and the railway terminus, was by then German by birth and language. The German Consul even opened a recruiting office, at which he enrolled British African natives for service in the German East Africa forces.

We have jumped to the year 1911. Let us see what was the position then. The combined value of imports and exports through the port of Mombasa had risen to 2½ millions sterling. The cotton crop of Uganda had increased from the 200 bales of 1906 to over 15,000 bales. The white settlers' coffee plantations were a proved success, though hardly in bearing to an extent that could give a surplus for export. Sheep-raising was beginning to be doubtful, ramie fibre had gone, but cattle diseases were being overcome, and grading up from local stock was looking well, and has since done better. Sisal hemp, of which our German East Africa neighbours were producing 15,000 to 20,000 tons annually (the German Navy was prohibited from using rope made from any other), was successful beyond question. Analysis of East African wattle bark showed it to carry more tannin than the best Natal product. The British East African natives, especially in the Lake and Mount Kenia provinces, were producing oil seeds, beans, and potatoes in quantity and buying trade goods freely. I happened to be passing Aden and tried to persuade an Indian merchant there, who was supplying the garrison, to get his stocks from British East Africa. His reply was, "It is no good; the people here will only eat potatoes from Nairobi." I had not a map handy to give him a geography lesson, but I was satisfied with his answer.

Larger matters had not altogether slumbered. Mr. Churchill had travelled through from Mombasa to the Sudan in 1908, and the short route to the Congo State was projected. This was to be the Busoga Railway, connecting Lake Victoria with Lake Chioga, with a steamer service on the latter to Masindi Port, a motor road thence to Lake Albert, and steamers on the latter to connect with the Congo shore. All this was to become an accomplished fact by 1913-14. In 1911 Lord Kitchener travelled through from Egypt *viâ* the Sudan, Lake Albert, and Uganda to Mombasa. Incidentally, as is well known, he became an extensive landowner in British East Africa, and his coffee plantations, cattle farm, maize-drying sheds, cattle dip, irrigation dam, and other estate developments are likely, by their influence and completeness, to play a big part in the scientific development of the country. The link established between the Sudan, East Africa and Uganda, by Lord Kitchener's tour, is suggestive, and already not without signs of significant development.

In this year also, 1911, the Union Castle Mail Steamship Company, famous for its part in the history of South African development, had commenced a service to Mombasa *viâ* the Suez Canal. It was truly British pluck to come on, without a penny of mail or other subsidy, and to challenge the German ships, albeit in a British colonial port. Should these words sound strange, remember that in our ports our Government gives equal hospitality to all. But to trade in the East African ports, the German Government was giving to its steamers a subsidy of nearly £90,000 per annum.

By the middle of 1912 things were humming, not only in the two British territories, but among our neighbours, south, west, and north. European and native developments were giving real results. The imports and exports through Mombasa exceeded three millions sterling. The Uganda cotton output was worth a quarter of a million—20,000 bales—and quantities of oil seeds, beans and other produce were being exported. Land values for European settlement quadrupled. Herr Dernburg, the German Colonial Secretary, toured through British East Africa and Uganda. He praised everything and everyone, and especially thanked Great Britain for having made it possible for the German Lake regions' produce to reach the outside world over the British railway. On no account, he declared, would Germany commit so unfriendly an act as to extend a competing line from the German coast to Lake Victoria. Then he went on to German East Africa and put in hand a survey for that selfsame railway. He expedited the extension of their main line *viâ* Tabora to Lake Tanganyika, and ordered it to reach the latter, without fail, by 1914—a significant date, which was duly kept. Herr Dernburg began to prepare the German coast port of Dar-es-Salam for the future, by providing a floating dock and other harbour facilities.

An incident about that time was a small local trouble in Zanzibar. A few discontented Arabs threatened the local authorities of the island, which was, and is, under British protection. A party of German troops arrived from their mainland opposite, offering their help to keep order. By remarkable foresight, they had started from Dar-es-Salam before the trouble in Zanzibar began. The British already had the situation well in hand, but I believe it was quite hard to make the Germans understand that they were not wanted.

In the Belgian Congo State, on the west of Uganda, the difficulties of administration in an area so remote had given opportunity for cruel and selfish conduct to some miscellaneous individuals whose hunting ground is always the country where there are fewest policemen. One can imagine that the highly-coloured and persistent reports of atrocities, which then so nearly caused ill-feeling between England and Belgium, were pleasant reading to the Wilhelmstrasse and the editors of the Wolff Bureau. Prince Albert of Belgium would no more take these matters through the eyes and reports of others than he, as King, would share by proxy in the gallant deeds of his army to-day. He just went to the Congo to see for himself. Payment in trade goods was abolished, traders were promised free entry—and have been given it—and since 1912 a steady and increasing flow of traffic of goods and persons has been passing between Mombasa and the Congo State by the route which Mr. Winston Churchill had projected four years before—the Uganda Railway, Lake Victoria, Lake Chioga, the Masindi road and Lake Albert.

Turn now to the north, where the Nile connects Uganda and the Anglo-Egyptian Sudan. The Uganda Government steamers run from Lake Albert to Nimuli. The Sudan steamers traverse the 1,000 miles of navigable water between Khartum and Gondokoro. Between Nimuli and Gondokoro occur 107 miles of rapids. But 107 miles is "across the street," when speaking of half a continent, and that obstacle cannot block

the way for long. The first step is already taken. On the death of King Leopold, the Lado Enclave, lying along the west of the Nile in this region, reverted to British rule. This area has been divided between Uganda and the Sudan, and the southern boundary of the Sudan moved south to the latitude of Nimuli. Thus the cataract section is now wholly within the Sudan administration, which will no doubt find a speedy and efficient way of dealing with it. Then will come the development of the Bahr-el-Gezel region to the west, which reproduces the features of the fertile swamp region of Lake Chioga in Uganda. Lake Chioga is now giving the Empire nearly half a million pounds' worth of cotton per annum. Would that Samuel Baker was alive to see it! Who can say what the Bahr-el-Gezel will do, with fifty times the area, before fifty years have passed? This must find its gateway through either Mombasa or Port Sudan, it matters little which.

Again follow the map round, and you find the Abyssinian frontier, with a road running north and south connecting that land of mystery with the Uganda Railway at Nakuru. Along that road pass horses, mules, cattle and merchandise. Further east, the valley of the Juba River divides British East Africa from our friends the Italians, and gives 200 miles of navigable waterway to bring their traffic to the British port of Kismayu, on the Indian Ocean, and thence by coasting boats to the ocean steamers at Mombasa —I repeat, the scheme of Tewfik has been realised, but not by Tewfik.

I have said that British East African trade had now topped the three million mark. Not only so, but the revenue of British East Africa was balancing its expenditure, and Mr. Harcourt could abolish the Imperial grant-in-aid. Most significant of all, the German steamers were now carrying away less than 50 per cent. of the produce, instead of nearly 100 per cent a few years earlier, so they increased their sailings and their Government maintained its subsidy. The Union Castle Line put on larger steamers, and ordered larger ones still, but had to ask its shareholders to pay the working loss.

But at last the British Government, which had watched so long, was to show that it had not watched in vain. The menace of Dar-es-Salam was not to go without reply to its floating dock, its feverish railway extensions to the Lakes, and its overflow of German traders into the British areas. A Governor was appointed to British East Africa, Mr. (now Sir Henry) Belfield, who had taken no small share in the creation of one of Great Britain's most successful Imperial businesses, the Federated Malay States. Mr. Alfred Lyttelton came out on a visit, and combined his holiday with shrewd observation and a determination that party politics should have no part in putting the shoulder to the wheel. Lord Kitchener went to Egypt, and the Sudan felt his stimulating presence. The East African railway system was overhauled by Mr. Blake Taylor, fresh from responsible work in India. He found that the nominal railway profits of preceding years had been largely created by using up capital, for 10 per cent. of the rolling stock of 1902 had disappeared through old age, and the rest were on their last legs—or wheels—and practically none had been replaced. The Lake ports, the main line, and the harbour of Kilindini, the port of Mombasa, were hopelessly congested. Mr. Harcourt took prompt steps, rolling stock was ordered, and the Colonial Office sent out its consulting engineer, Mr. Maurice Wilson, to investigate the harbour question, the vital link between the system of inland communications and the means of ocean transit. Both of these may be perfect, but if the bottle neck be inadequate, the traffic cannot squeeze through save at great cost and loss. Competent calculation has shown that the delays to the steamers and the damage and inconvenience to trade were equivalent to a tax of 5*s.* on every ton of import and export cargo; indeed, worse than a tax, for it is sheer waste, and goes into the pockets of nobody, and handicaps the products of East Africa on the markets of the world. No wonder Herr Dernburg was all smiles when he went on to give an extra push to Dar-es-Salam in the race for the great prize, trade predominance as the gateway for half a continent.

And so we reach 1914. The Mombasa trade was now nearing five millions sterling, and the Uganda cotton crop about 50,000 bales. The natives were enlarging their wants and buying better clothing, bicycles, cigarettes, and quantities of soap. Some chiefs even bought motor-cars; one of them bought two, for he said he had heard that in England the lady wife must have her own conveyance. In the Nyanza province Mr. Ainsworth's natives raised and sold 18,000 tons of exportable produce. The European population increased by 30 per cent. in a single year, and their coffee and sisal hemp fetched top prices at home. The Congo transit traffic was responding to the improved communication facilities. In March 1914 the new 11,000-ton steamers of the Union Castle Line

arrived at Kilindini amid great enthusiasm. The Governor, Sir Henry Belfield, announced at a dinner on board the "Llanstephan Castle" that where private enterprise had led the State must not be behind. He added that where State funds were not available for the great developments needed, private capital must be allowed to do its part. And His Excellency informed East Africa that Mr. Harcourt was about to bring in a Loan Bill in the Home Parliament, whereby three millions sterling would be provided for harbours, railways and other great public works in the East African Protectorates. The plans for Kilindini harbour were approved, and a survey put in hand for a branch railway from Nakuru. This was to cross the Vasin Gishu plateau, a thickly-settled European area, traverse the timber forests of the Ravine and open up the productive North Kavirondo native region. It is easy to foresee the natural terminus of this line on Lake Victoria at Port Victoria, the originally projected terminus of the main line. Port Victoria has 16 ft. of water, which compares with 7 ft. only at Kisumu, the present terminus. Kisumu has done great work with its 1,000-ton steamers on the Lake, but has reached its limit. The day will come when 3,000-ton boats will steam in and out of Port Victoria bay, and that place may take rank as—shall we say—the Chicago of Equatorial Africa, the collecting point for the entire Lake region and the Eastern Provinces of the Congo State.

And here let us make a simple calculation. There are fifteen million people in British East Africa, Uganda, the Eastern Congo, and the German Lake districts, for all of whom the port of Mombasa is their shortest route to the outside world. The consumption of cotton goods is the best test of development. These fifteen millions of people received in 1913 just half a million pounds' worth, say eightpence worth of clothing for every man, woman, and child for one year. In more forward regions of Africa the figure per head is three to four shillings' worth per annum —a not very extravagant millinery and tailor's bill. And other trade, import and export, goes in proportion. Reckoning nothing for the further advances of civilisation, there is thus, within assured view, a jump in the trade of those countries from the five millions of last year to something like twenty millions sterling, and it depends first and foremost upon communications. Ten million pounds' worth of food and raw materials to come each year to the people of Europe, and ten million pounds' worth of home manufactures to go out in exchange. And with trade follows the *Pax Britannica*, equal opportunity for all, and the creation of surplus revenue to lay out upon fighting climate and disease, to build schools and hospitals, and to pay for the equipment of civilisation with which the European settlers are establishing a strong and permanent colony in the area climatically suited to them.

What is needed now to reach the goal? Above all, no relaxation of effort, for nothing is so certain as that you cannot stand still. If you do not progress you go backward. The harbour must be gone on with and its present handicap on trade abolished. East African products have just such a value as they can command in competition in the world's markets against the products of older countries, the latter in their millions of tons, and we, as yet, only in our thousands. We need good ships to carry our thousands, but if they charge enough to cover their expenses our products cannot pay it, or are limited to the output of areas close to the railways and the Lakes. Reluctantly, but deliberately, I assert that the economic progress of British East Africa and Uganda has owed more to the big German shipping subsidy than to any other factor, except of course our railway. Even £50,000 per annum, and it was much more, spread over the whole traffic in the reduction of freight rates below the cost of working the ships, provides a margin upon which millions of pounds can be embarked in East African trade and development. The Imperial British Government has invested ten millions of money in the railway and in settling the country. It holds the doorway for millions of people in our own and adjacent territories. Will it not safeguard its investment and step into the breach, now that the German ships and German shipping subsidy have gone?

Then, incidentally, I would plead for a more effective realisation, in the administrative machine, of the essential unity of the areas we are discussing. The system of distinct local governments, two treasuries, two Customs departments, for British East Africa and Uganda, makes for separation rather than for co-ordination on the spot. When, for example, the whole of the railway revenue derived from the traffic of both the British Protectorates and from our neighbours, all goes into the treasury of one of the Protectorates, the other is apt to doubt its own recognition in the general scheme.

Before I close, let us look again at the map. Observe how closely Egypt, the Sudan, Uganda, British East Africa, the eastern provinces of the

Belgian Congo, and the Lake regions of German East Africa, are knit together by natural lines of communication and the last four of these countries have their doorway at Mombasa. I have tried to indicate how closely connected has been their development thus far. May it not well be that their future may take shape in some form of economic federation of North-East Africa?

[The paper was illustrated by lantern-slides lent, or produced from photographs kindly lent, by the London agency of the Uganda (Government) Railway Department, the East Africa Estates, Ltd., the East Africa and Uganda Agency and Development Co., Ltd.; the British East Africa Corporation, Ltd., and the *African World*, per Mr. Leo Weinthal and Mr. J. Auerbach. Exhibits of produce of East Africa and Uganda were lent by the British East Africa Corporation, Ltd., and the East Africa and Uganda Agency and Development Co., Ltd. The Union Castle Mail Steamship Company, Ltd., exhibited oil paintings of Mombasa harbour. The thanks of the reader of the paper, and of the Council of the Society, are gratefully accorded to all who thus kindly assisted.]

DISCUSSION.

The Chairman (Sir Owen Philipps) said that at a time like the present, when everybody's attention in the country was rightly directed to the feats of our Army and Navy, especially our Army on the Continent of Europe, one was apt to overlook the fact that there were great doings on the African Continent; first in Togoland, which had now ceased to be a German colony; then further south, the Cameroons, where the capital, Duala, was now under British control and declared open to British trade; further south still came the British Possessions, where, under the magnificent leadership of General Botha and General Smuts, the rebellion was rapidly being quelled, and the whole country was joined together in suppressing the invasion from German South-West Africa, a district which he believed would before long be added to the Union. With regard to British East Africa and Uganda, the author had very graphically succeeded in bringing into the short space of less than an hour a most excellent and lucid account of the progress and development of those countries. It was specially important that the attention of Great Britain should at present be drawn to East Africa, because the Germans had invaded that colony. It should be thoroughly understood what a very important Imperial asset East Africa and Uganda were to the Empire, and he hoped that they would not only be maintained and developed but still further increased by the addition of the neighbouring German colony.

Lady Lugard said she had no idea on entering the meeting that she would be asked to speak, and felt herself to be really quite unworthy to detain the audience even for a moment. Major Leggett had given so clear and admirable an account of the development in East Africa during the last few years that everyone had been deeply interested, and she was sure that no one would be more interested than her husband had he been able to be present. No one had taken a deeper interest in Uganda than he had, and she well remembered on first making his acquaintance that one of the most interesting things he told was how he went into Nairobi and made blood brotherhood with the chief and bought a small area, now Nairobi, thus adding the first bit of that country to the British Empire. He came back, a silent and shy young captain, to find that upon him had been laid the onerous duty of going through England and Scotland addressing crowded assemblies in order to raise a feeling in favour of keeping Uganda, and so well succeeded that the Government of that day, which had made up its mind to abandon the country, determined to hold it. That was the only sort of claim, as it were by proxy, that she could be supposed to have for saying a single word in the discussion, but she was certain she was expressing everybody's feelings when she said how much interested they had been in hearing what Major Leggett had to say to them.

Sir Harry Wilson, K.C.M.G., said he had really far less claim than Lady Lugard to speak at all upon the subject of East Africa and Uganda because he had simply been there as a tourist for a very happy three weeks, travelling up from Mombasa as far as the Lake, crossing the Lake, and coming back again with various short diversions on either side. That afternoon, in the murky atmosphere of London, it was delightful to be transported by the paper and the beautiful pictures on the screen to the sun-washed spaces of East Africa and Uganda, and the audience were greatly indebted to Major Leggett for the admirably clear description he had given of the development of the country and the wonderful possibilities which he had foreshadowed. There was one point in the paper which he wished to take up, not as one having anything to do with East Africa or Uganda, but as one concerned with the neighbouring territory of Nyasaland and the adjacent territory of Northern Rhodesia. Major Leggett had mentioned that the Imperial Government had brought in a Bill for the loan of three millions to the Protectorates, and particularly the Protectorates of East Africa and Uganda, but he believed he was right in saying that about £800,000 of that loan was to have been devoted to the neighbouring Protectorate of Nyasaland, to be spent on roads and railway extension, and it would be a very great disaster to that Protectorate, as it would be to British East Africa and Uganda, if the Bill did not become an Act. Everyone in the room interested in any of those three countries would agree with that, because the failure to raise the loan would mean a most unfortunate stagnation at a time when the Empire ought not to be standing still but carrying on "business as usual." He had felt a great deal

of envy in looking at the pictures of the Uganda Railway, because in North-Eastern Rhodesia at present there was no railway at all, and the goods so painfully produced in that part of the world had to go down to the Zambesi, over a bad Portuguese road for 220 miles, then by a long stretch of river to Chinde, and from Chinde to Durban, and so home. He wished publicly to express the great debt which the inhabitants of the country owed to Sir Owen Philipps for the kind interest he had consistently shown in meeting their efforts in that direction. He was sure Sir Owen Philipps would be glad to know that last year, in a limited part of the territory of North-Eastern Rhodesia, something like £5,000 to £6,000 worth of cotton was grown, although cotton-growing was only begun there as a commercial enterprise in 1910. That part of the country also produced a large crop of tobacco, and this year he was told by his manager that there would be a very much larger acreage under tobacco. Railway facilities were absolutely essential for that district of the country. The present meeting would be a very valuable one if, as its outcome, the three Protectorates should join together to see that they were not left out in the cold but that the Loan Bill was carried through, and he could say for himself, and he was sure he might say for his friend, Mr. Birchenough, who had had to leave the meeting, that they would only be too glad to take a part in any movement in that direction.

Mr. Alfred Wigglesworth thought the paper was of exceptional excellence, and did not think it would be possible for anyone to have given so comprehensive a view of British East Africa and Uganda in such a short space of time. The audience had gained more knowledge in one hour than they could have obtained in weeks and months of travelling throughout the country. He wished to refer to a subject with which he was familiar in connection with the development of the Protectorate, namely, the fibre business. It was only in 1906 that the first plants of sisal fibre were introduced from German East Africa and planted in the highlands and in the coral lands of the coast as an experiment. Everybody laughed at the planting of sisal in the highlands, in land so rich that it would grow almost any crop, because sisal was known to be a plant that would only thrive on coral soil or land of singular infertility. The plant, however, prospered to a degree which no one would have imagined, and the industry developed. Machinery was brought out from Germany, as that country appeared to be the only country producing a machine which could successfully prepare the fibre, and the product was sent home. The first batch arrived in London less than three years ago and realised a very handsome price, and since then the industry had increased to a point at which he estimated there were over 10,000 acres of the plant in the coast lands and the uplands, producing in the present year something like 3,000 tons of the fibre. Taking the produce of each acre as three tons and the price at somewhere about £30 a ton, the value of the sisal industry to-day was close on a million pounds in British East Africa. That was as great a monument to the energy and enterprise of the planters and settlers as any other product produced there. He agreed with all that had been said with reference to Sir Owen Philipps and the great work he had done in the development of East Africa. Without transport the settlers might produce plenty of goods, but they would not be able to market them at prices which would show a profit. That was particularly the case with such things as wattle bark, which was not very valuable per ton. The future of East Africa was largely dependent upon binding it up with the rest of the Empire by a good service of steamers, with freights reasonable enough to put the product on the home markets in competition with the products of other countries.

Professor W. J. Simpson, C.M.G., M.D., said his visit to East Africa and Uganda hardly entitled him to speak on the economic development which had been so admirably described by Major Leggett; but he naturally formed impressions, and was particularly struck with the newness of things, the rapidity of the growth of the commercial and agricultural interests of the country, and the rapid development under very great difficulties. It was only a short time ago that the inhabitants were trying to exterminate one another in inter-tribal warfare, and were the subjects of slave traders; but now the Uganda Railway stretched from Mombasa to the shores of the Victoria Nyanza, and throughout the country there were large cattle ranches and sheep farms, and the natives were raising large crops of maize and other things for exportation. There were also plantations of copra, coffee, sisal and wattle, and the immense undertaking of the Magadi soda works. Some of the inhabitants believed that Nairobi would ultimately become the hub of the universe. Across the lake, in the eastern Province, the population, which was a naked one, was growing cotton in patches from half an acre to three acres, and was transporting it to the ginneries recently established, from which it was sent away to the Lancashire mills. The peacefulness and great development of the country showed the British genius for governing native races and for pioneering work. He had travelled in most parts of British possessions, and everywhere had found German commercial travellers. He remembered once meeting an energetic British traveller, but he was travelling with whisky. The German commercial travellers were well-trained men, who went to great pains to discover what their customers required, and took care that the firms they represented sent out the things that were needed. One exception to that was the corporation to which Major Leggett belonged, because the energetic agents of that Company were always at work endeavouring to see for themselves how matters stood. He felt strongly on the subject, because it had a very bad

effect. In one of the remote places of Uganda he went into an Indian bazaar to see what goods were being sold and where they came from. Loin cloths he found came from Germany; some of the cotton goods came from America, but the majority from Austria; sewing machines came from Germany, as did also brass and iron wire so much used for ornament by the women of the country; scented soaps came from Hamburg. There were some things from England, such as bicycles and Lipton's tea. Ninety per cent. of the cotton from Uganda went to the Lancashire mills, and one would naturally think that the mills in return would supply a large quantity of the cotton cloth; but only one-fifth of the quantity imported into the country came from Great Britain. He felt certain that if the country did not wake up in a commercial respect after the war we should be outstripped by those who sent well-trained commercial travellers to the country.

Colonel C. E. Yate, C.S.I., C.M.G., M.P., in moving a cordial vote of thanks to Major Leggett for his most interesting paper, said he had never been to East Africa in his life, but he could honestly say that no one in the House of Commons voted with greater enthusiasm than he did for the grant of the three-millions loan to East Africa and Nyasaland. He was one who believed that the State should help in the development of our possessions and protectorates abroad in every possible way, and if there was one thing more certain than another it was that he should continue to back up the development of Uganda and East Africa in every possible way. He had followed the history of Uganda and the East African Protectorate since his early Indian days, and could remember well, during the building of the Uganda Railway, losing one of his best shikaris, who was sent for from British East Africa by one of the railway engineers to help him to rid the country of lions and other wild animals that were interfering with the work. He had followed the history of the country through its career to the present day, and was watching the present military operations there with the greatest interest. He was sure they would all join in the wish of the Chairman that the result of those operations would be the considerable enlargement of the East African Protectorate. It was desirable that the Protectorates should be joined together and communications opened up, and he hoped that the obstacles that had hitherto been placed by the Germans in the way of that grand idea of Cecil Rhodes of a Cape to Cairo railway would be before very long entirely removed. Colonel Yate, on behalf of the Society, also thanked Sir Owen Philipps for presiding.

Sir Frederic W. R. Fryer, K.C.S.I., seconded the motion. He said he had never been to East Africa or Uganda, but he had often heard Major Leggett's name in connection with those countries, and had taken a great interest in their development. He felt sure that everybody present had been in no way disappointed in their expectations of learning a good deal from the paper which had been read that afternoon.

The motion was carried unanimously.

Major Leggett, in reply, said it was a great honour to him to hear the kind words of Colonel Yate and Sir Frederic Fryer, and to receive the appreciation which the meeting had so kindly given to him. He was very thankful for the interest that had been taken in a subject on which he and others interested in the country felt very deeply. With all that had been said in the course of the discussion he thoroughly agreed. There was a great deal to be done not only by Governments but by individuals.

Mr. Maurice F. J. Wilson, M.Inst.C.E. (of Messrs. Coode, Matthews, Fitzmaurice and Wilson, Ltd., Consulting Engineers to the Colonial Office), writes:—The Colonial Office are quite alive to the necessity of deep-water accommodation at Kilindini, and towards the latter end of 1912 they requested my firm to report upon the whole question. Consequently, I went out early in 1913 in order thoroughly to investigate the site and obtain particulars with a view to preparing the necessary report. The site at Kilindini proved to be an excellent one for the purpose. It offered a large area of deep water, perfectly land-locked and sheltered, where deep-water quays could readily be constructed in direct communication with the main line of the Uganda Railway. Extension to such quays could be made as the requirements of trade called for them. A report to this effect was sent in to the Government, and it is hoped that the work may be proceeded with as soon as circumstances permit.

EIGHTH ORDINARY MEETING.

Wednesday, February 3rd, 1915; George R. Parkin, C.M.G., LL.D., D.C.L., Organising Secretary of the Rhodes Scholarship Trust, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Buckland, James, 28, St. Thomas's-mansions, Westminster Bridge, S.E.

Khan, Choudhri Md. Aziz-ulla, Sahawar, Etawah, U.P., India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Bailey, Hollis Russell, 19, Congress-street, Boston, Massachusetts, U.S.A.

Barnard, George E., Park Estate, St. Lucia, British West Indies.

Brandt, Richard Frederick William, B.A., 5, The Boltons Studios, Fulham-road, S.W.

Cherry, Albert, Venezuela Central Railway, Caracas, Venezuela, S. America.

Cottingham, Walter H., Woolley Hall, Maidenhead, Berks; and The Sherwin-Williams Company, Cleveland, Ohio, U.S.A.

Duke, Sir (Frederick) William, K.C.I.E., C.S.I., 11, North-street, Westminster, S.W.

Harris, William A., A.M.I.Mech.E., St. Lucia Usines and Estates Company, Ltd., Castries, St. Lucia, British West Indies.

Heynes, James Baylis, British Vice-Consul, Messina, Sicily.

Hume, F. Charles, Jun., First National Bank Buildings, Houston, Texas, U.S.A.

Lloyd, Professor John Uri, Phar.M.Ph.D., LL.D., 3901, Clifton-avenue, Cincinnati, Ohio, U.S.A.

Lovett, Major-General Beresford, C.B., C.S.I., 59, Madeley-road, Ealing, W.

Morgan, Edward D., 170, Summer-street, Boston, Massachusetts, U.S.A.

Perkin, Dr. F. Mollwo, F.I.C., F.C.S., 199, Piccadilly, W.

Powell, Christopher Charles, 52, Langdon Park-road, Highgate, N.

Power, John Joseph, K.C., M.A., LL.M., D.C.L., P.O. Box 532, Halifax, Nova Scotia, Canada.

Shaw, George L., Antung, Manchuria, China.

Watson, F. Mackman, "Selwood," Rotherham.

Wood, George, 626, Chestnut-street, Philadelphia U.S.A.

The paper read was—

EXPANSION OF BRITISH INDUSTRY AFTER THE WAR.

By Octavius Charles Beale,
Past President of the Australian Manufacturers' Association.

Our chief subject for consideration to-day will be the methods by which may be attained that expansion of industry throughout the British Empire which is the aim of all loyal citizens. We shall not attempt to adduce in exhaustive form the countless spheres of activity which may and ought to be included in our future efforts, and whilst indicating some of them we shall suggest the direction of our energies so as to tend to a comprehensive result. Even in the territorial sense there will be acquired through the Great War further fields for enterprise, but we have also to reconquer lost or undeveloped domains in the area of manufacturing industry itself.

Britain the Mother of Invention.

You have all heard to nauseation that our British industrials, employers and employed, lag far behind the foreigners—more especially our esteemed friends the enemy—in respect of technical education. Our workers, forsooth, in their ignorance, indifference, indolence, above all by their trade unions and combinations, are spoiling everything. You were told upon authority the other day that the Germans have succeeded over the English because "they know all that there is to be known" in what they undertook. Yet our nation has taught the world!

Authors, poets, philosophers, acclaim this by common consent to be the Iron Age. Very good, who started and developed it?

In the past, sagacious statesmen, brave and faithful generals, invincible admirals, upheld the honour of our race, made stable the Imperial sway, and spread over all the world the glamour of the British name—wider far and even more glorious than the *Romani nominis umbra.* Soldiers, sailors, statesmen, not merely traders, built up the British Empire with the indispensable assistance of the assiduous inventor and the patient industrial at their back, at home. Thus the second Abraham Darby, of Coalbrookdale, in the former half of the eighteenth century, was the first man effectively to smelt iron with coal in the form of coke, instead of charcoal. His son built in 1767 the world's first iron bridge, which, spanning the Severn, has withstood for a century and a half the stress of traffic and the storms of time, and so these brown-coated Quakers in their earnest simplicity became the true founders of the Iron Age, and in high measure of their country's greatness. Yet their very names, and those of their compeers are all but forgotten by the world at large.

At the end of the seventeenth century the first Abraham Darby, having started a brass foundry, had devised means for making articles out of iron that had been usually made of bronze. He also invented a method of casting hollow-ware in sand, and so became in quietude and obscurity an epoch-making personality. Some day, perhaps, a superfluous and voluble politician will be lifted off an undeserved pedestal so that one or other of these genuine empire-builders may be given his due.

Britain, not Germany, Leader in Technical Instruction.

We all know how steam-power was practically introduced and developed in Great Britain, how railway enterprises fought down opposition, how ninety years ago road-cars not ineffectively driven by steam were crushed out of existence by adverse legislation, how the use of electricity was developed, and electro-plating made practical

—and all in England. We know who laced the earth with marine cables; who advanced mining and metallurgy all over the planet; who applied chemistry and extended the purely scientific knowledge of it; who discovered aniline dyes; who built and drove the first steamers around the globe; invented spinning and weaving machinery, sheet window glass, and lighthouses; who also practised well-sinking, irrigation, acclimatisation, stock-breeding on a planetary scale; who improved wheats, and who carried on exploration of the waste places of the earth. We know, too, who can justly claim the change from wood to iron, and from iron to steel in shipbuilding. Our British people of all ranks of society were either first or foremost in each of these and other departments of activity, the very enumeration of them dazzling the mind.

And we know now how the well-armed and well-armoured German plagiarist, who has been called "the Chinaman of Europe," succeeded against Englishmen in England, whose vain boast has been that they had no industrial protection, very little military but far too much naval!

How Germany Stole Marches.

Well, then, if there be defect in the technical instruction to our workers, if there be default in the due reward to and encouragement of industry, together with that adequate furtherance and protection by legislative measures which Germany and all the important foreign nations enjoy, blame must attach to others than those who have suffered. The favourite attribution, as already said, is not to those who have withheld the benefits, but to the workers who have been thus deprived of opportunities so freely and generously provided everywhere outside of Great Britain. To ignore this phase of the subject would be, at least to oversea residents of the British Empire, to shut our eyes to the *fons et origo mali*. To-day we cannot enter upon the arguments *pro et contra*, for that must be left to our public men.

It is not to be feared in Greater Britain across the seas that industries, the people's only sound and sure means of livelihood, will be left to what has been called the "free play of natural forces." These are in essence highly artificial, and have been seen on occasion to consist of cunning with capital applied to the destruction of competing activities. Aggregations of both have controlled by varied methods departments of industry outside the producing States themselves. We have witnessed the spectacle of a German private firm debauching by bribes high officers in Japan so as to secure business in iron and steel products intended for civil and military use in the Japanese Empire. An intensely patriotic, sensitive and self-denying people felt themselves outraged when, by a chance, discovery was made. Justice was done, and righteous anger was aroused against the Germans which is not soon or easily to be appeased. Such commercial forces, however, are seen to be natural enough, or artificial enough, just to the extent that prepossessions will leave our vision clear. The firm alluded to was shown to have a carefully organised department for the acquisition of business, *fas et nefas*, and a stupendous capital. The incubation of a world-war might not be beyond its dreams.

It is no small matter that the metal products of an important mining field, like Broken Hill, the chief source in the world for zinc, and prolific in lead and silver, should be controlled by Germans resident in Germany. And so with other British mines that yield abundantly. By cables we are informed that the Commonwealth Government has tackled the question with the resolve to have the treatment of Australia's concentrates, hitherto shipped to Germany in quantities of several hundred thousand tons per annum, dealt with in the country of production or in Great Britain. From whatsoever type of neglect, political or personal, but at all events national, the British Empire has let slip in very large measure control of this stream of wealth.

How to Keep the Money in the Family.

British industry will expand after the war beyond doubt, but it is incumbent upon us to "apply our minds keenly to consider" the channels for expansion before the war closes, because the rush and demand, according to experience after other great wars, will be so great that preparations for new work will be costly to the extent, perhaps, of exclusion. Here, then, in metals is a sphere for present action.

Canada.

In some countries there are placed export duties upon ores to the end of securing that the handling shall be done in the producing country itself. The effect of such a provision is, *inter alia*, that the refined metals are available on the spot for use separately, or with admixture of others. Canada produces her own iron and steel, and to obtain the highest qualities, or kinds suitable to

special purposes, she must have chemists and metallurgists with the major and minor metals immediately at their disposal. Hence she can obtain as citizens men who are most advanced in applied science and can fully remunerate them. Their activities, besides teaching others, require collaboration in diverse branches of work and of instruction, to the huge benefit and strength of the Dominion. Where a country itself derives the chief advantage out of its own productions, there may surely be expected an expansion of them, especially those which, like metals, are basic to other industries. So in Canada, apart from gold, the metal and mineral production during five years up to 1912 shows a gratifying increase. The grand total for 1912 was $133,000,000, an increase over the preceding year of $30,000,000, say 26¾ millions and six millions sterling respectively. And Canada, as you are well aware, uses discrimination in every just form in the political treatment of her industries, so that they may be made remunerative and attractive to her citizens and to would-be immigrants.

As to the manufactures of Canada, comparing the year 1910 with 1900, the consequent increase is enormous, not to say startling, for the figures have much more than doubled. In the decade they have been raised from £96,000,000 to £233,000,000, or an increase of over 142 per cent.

Australasia.

Turning, then, to our other colossal Dominion across the seas, the Commonwealth of Australia, we find that our imperial industries proceed upon similar lines of development. There, too, all kinds of discouraging prophecies were hurled at advocates of the expansion and differentiation of industry, prophecies that now are seen to be so absurd and humiliating to their authors and propagators that it is unkind to mention them. A great coal-producing country, Australia imported coke for her mining and metallurgical industry. Customs duties were proposed and imposed, with the usual howl from vested interests. There are now long rows of coke-ovens, and the fuel is cheaper, of course, than ever. It is known to be a grazing country of some importance, with a practical monopoly of merino wool, and depasturing (if we include New Zealand) just twice as many sheep as the whole of the United States of America. On the coast-lands dairy cattle luxuriate. But the Commonwealth imported preserved milk from Switzerland, and when duties were proposed on canned milk, prophets within my own hearing set up a pitiful lamentation about the cruelty to babies. Vested interests again. But the *soi-disant* Swiss packers have now extensive factories in Australia, whence they export canned milk to many countries, and of an absolute purity that is controlled by the State, whilst the babies have not gone short for an hour. The preserving element is Australian-grown sugar.

It is safe to say that no controversy has been more prolonged and embittered in Australia than that of growing cane and manufacturing sugar by white labour exclusively. Yet the coloured labourers have been as far as possible repatriated, and whereas in 1906 the quantity of sugar produced by them was over 100,000 tons, in 1913 it was only 6,000 tons. As that has declined towards vanishing point, so the total product has been raised until it reached last year nearly 250,000 tons, and, as we see, by British activities. Again the prophets were confounded, and a powerful demonstration made of the efficiency of British brain and brawn. Rest assured, ladies and gentlemen, that even in this sphere of action there remain further areas for progress, that the severity of the work will be reduced by devices and contrivances, whilst it may fairly be claimed that in the department of chemistry as applied to sugar production and waste-saving therein, Australia is not surpassed. In conquering that field the Empire is served directly and handsomely.

A few years ago an English expert upon wheat-growing surprised his hearers in this very room by telling them that tilling and harvesting in Australia were conducted at a lower cost than in any part of the world. Yet we all know that the remuneration of labour is there happily high. It was a frequent prophecy, settled by political economy to methodical and irrefragable proof, that the Australian colonies could never become grain-exporting dominions in competition with India and Russia. As chief objection, the states embraced by the geographical term Australasia were so sadly British and possessed of the idea that workers should be well paid. Only when wages should fall, as they surely would, to the European level could they hope to enter the market. As we all know, these obstinate British were not guided by professors of political economy, have never been so guided in the very least, but set themselves to think all afresh, just like their brethren and forefathers for ages. They did not even consult the allegedly profound thinkers of Germany, as

they might. No, the problem was, with little means but much faith in themselves and love of their race, how to conquer those glorious domains by sheer industry whilst facing Nature in her most appalling austerity. They invented the stump-jumping disk-plough and the stripper harvester—with other tools—so that they also, as we started by saying, helped to teach the world.

But I read in the Chicago papers, when in that city a few years ago, that the big harvester combines of America had resolved that the agricultural implement factories of Australia must become mere repairing shops for American-made machinery. Left to the free play of natural forces (or artificial as aforesaid) that is exactly what would have occurred. By all purely philosophical and high economic argument of the political variety, those producers of useful tools, with further ever-impending novelties of invention in Australasia, would have been wiped out of existence. The farmers would thenceforward become vassals of the American exploiters. The proposition was for the exploiter only too sweetly simple. But the electors and their parliamentary representatives decided otherwise. They preferred to preserve and to expand the industry. Consequently Australian implements have had a very large sale in Argentina, in North, South and Central Africa, to the benefit of the Empire and the world. There remains one highly important improvement yet to be perfected. We are told that progress is being made towards the completion of an agricultural implement which will plough, cross-plough and harrow in one operation, leaving the land ready for the seeder. The extra power demanded is expected to be but slight, and that remarkable attainment will also be the product of British brains under a rational and genuinely scientific industrial policy.

Canadian agricultural machinery is to be found in use in quantities probably far larger than Australian all over the Empire, thanks to the determination of her men of enterprise and her legislators. Else, as all Canadians know, their country would be a mere appanage of the United States.

Foreign Monopoly of British Metals.

On December 10th, Mr. W. M. Hughes, Federal Attorney-General, speaking in the Commonwealth Parliament, said that "the investigation regarding the Broken Hill and other metal companies had not disclosed an offence against the law, but the facts showed, beyond all question, that German influence exercised a monopoly over the civilised world's base metal industry. The monopoly was so complete that it excluded effective competition.

"Peace held out no prospects satisfactory, or even tolerable, to the British and Australian interest, since it would only revive complete domination of the industry. The war would have been vainly waged, if, when victory at a dreadful cost had been won, we were again compelled to pour into Germany's lap the lion's share of the wealth created by Australian enterprise and Australian workmen.

"Germany determined, in effect, our mineral output. The position was intolerable. The Commonwealth had communicated with the Imperial Government strongly requesting co-operation in these matters, in which the interests of the Commonwealth and the Empire were so vitally involved."

Whether all this is illustrative of, or antithetic to, the glorious principle of *laissez-faire* and the free play of natural forces, must be left to the dialecticians to settle. Casuistry brings no cash to the honest workers, nor strength to the British Empire. The price of freedom is eternal watchfulness, plus keenly elaborated protection to our toilers by head and hand, as against their exploiters, be they German or American bankers and metal-jobbers, or both combined. The two in combination has been the actual condition of affairs. Whether a world-war counts among natural or artificial forces is also hard to say, but assuredly it has laid bare infamous machinations and has shattered what were thought to be impregnable commercial strongholds. It is in the power only of a people's combine—that is to say, a national government—to prevent their re-erection. Where a government actively intervenes by well-chosen measures the exploiter lays his snares in vain.

How Malaya Teaches the World.

Take the instance of a little State where the article involved is yet of Imperial, indeed world-wide, importance. Counting their chickens before they were hatched, the German-American metal-jobbers purchased lands in suitable positions to deal with the tin-product of the Malay States. It is as much as that of the rest of the world added together. All arrangements had been made with customary skill and audacity to exploit the producers—and, of course, the consumers. But the Government of the Malay States quietly yet firmly

entered the field, imposed differential duties upon the metal contents of the ores, to the effect of retaining the industry locally, and, further, of retaining control for the public benefit. Smelting works, the largest in the world, were erected by a British company at Singapore and Penang. In these works are smelted not only the local products, but to them are consigned tin ores from South Africa, some from Australia, and a good deal from the Dutch Colonies, for treatment. Seeing that the game was up, the poor German-American bankers were constrained to arrange for the sale of their lands, which were eventually taken over by the Government of the Malay States, which altogether is a very fine example of able British administration. Here let me interpolate that my own business friends who have come into contact with them find no words too emphatic to express their admiration of these able and courteous British officers, faithfully discharging their duties and dealing out to all an even-handed justice. Our people having built well, their structures withstand the earthquakes of Armageddon. But we can do more work on the same lines, as I hope to show, and on a comprehensive scale.

How to Throw Off the Foreign Incubus.

For some years past we have pressed upon the Government of Australia the advisability of inducing the local treatment of ores by placing export duties upon the metal contents, whilst allowing free export of the refined metals. I have myself co-operated with our Chambers of Manufacture and with Associated Trades Unions in the effort to localise the industry and thereby to remove it from foreign control. We collated and presented all the facts and figures, but our deputations to the then Federal Ministry received only the cold shoulder, so that the Germans remained in possession of the field. Not at all that these exploiters were intentionally favoured, but because false arguments prevailed. Take one for the sake of its significance as applied by our people all the time, and most of all in the homeland itself. *Ex uno disce omnes.* The Germans, we were told, could do something that we British in Australia could not do, nor for the matter of that the British in Britain either. And so the melancholy fact remains that the whole of the concentrates from the biggest mining field of the world in zinc, lead and silver have been sent to Germany for treatment. Further, the ore-contents, the metals themselves, were controlled—as the phrase goes—by Germans. In other words, they got the handling of the profits. Nor does the trouble end there, because the contracts for the sale of the ores, properly called concentrates, continue after the probable end of the war. Can a position be more wholly ridiculous, inasmuch as neither Germans nor Germany are held bound by laws, conventions or even sworn contracts under seal by their rulers ?

The thing we British could not do was, however, in the physical sphere. Very high temperatures are required in the treatment of the concentrates, and no British firebricks would resist them. But the manager of the largest company informed us that his people instituted a careful search for the material in Australia, which continent seems to possess every metal and mineral. The company purchased an area containing the desired clay. They had bricks prepared of it, after preliminary experiments, then placed a German brick on top of an Australian brick, subjected the two to extreme heat, and, finally, fused the German brick right over the British, leaving the latter unaffected. As before said, from one German lie learn the lot.

Australian-born metallurgists have developed to an amazing extent the saving of metals by floating them to the surface instead of depositing them. Where does the German omniscience come in that has been so unfairly and unwisely forced upon our acceptance of late ?

Once the legal minds have finished their important discussions as to how we can, and why we ought to, restrain ourselves by contracts which the other side regards as scraps of waste paper, it will be up to Great Britain or Australia, or both, to institute the smelting and refining of the metals already named. Meantime the Straits Settlements and the Malay States, as also New Caledonia and Canada, not adhering to the shibboleth of *laissez-faire*, or the supposed impropriety of the State interfering with "natural" forces, have made themselves—their citizens—quite comfortable. That the German-American banking and metal syndicates prefer their victims to be bound by the fundamental principle of political economy goes without saying. National economy, however, gets along much better when free to institute its own devices, and to adjust itself to the visible exigences of varying situations.

The Beneficence of Industry.

Abraham Lincoln declared, in a speech to his constituents: "No doubt you have all heard a great deal of the political economists. I

don't know much about them myself, because I don't read them; but this I do know, that when America sends a thousand dollars abroad for iron rails she gets the rails, but if she makes them herself she has the rails and the dollars too." That is true, but the apophthegm does not describe all the benefits by a long way. An important department of mining operations for metals is the production of chemical fertilisers, so that miner and farmer mutually assist one another. So, too, the flour miller returns the bran with its phosphoric acid to the stockowner, thus indirectly tending to sustain the fertility of the soil. Consequently, it is worth something, and worth much to a country, to establish, to preserve and to protect its individual industries, for hardly ever do they stand alone. All are more or less interdependent, of which countless illustrations can be supplied.

Not merely in the basic industry of metal-refining does the United Kingdom under stress of war find herself strangely deficient, but also in dye manufacture, of which we have heard so much. There again will dye-production not only train and remunerate a large number of chemists of first rank and other skilled employees, it will contain a department for the manufacture of drugs, beneficial and otherwise, besides stains and colours. Engaged in the utilisation of what was a waste product, it may well develop other savings, but in any case it will be a centre of invaluable practical instruction. All that is worth something, as advocated by the great consumers of dyes in Great Britain, namely the protection and preservation of the industry.

Dangerous Draughts through an Open Door.

Gathering now our threads together, we have seen that, without Teutonic boastfulness and bumptiousness, our nation has been in the past the world's great industrial inventor and instructor. Under the industrial policy introduced by Bismarck in 1879, which set out to found and further German industries in all departments, a stupendous success has been achieved. In iron and steel production Germany has distanced Great Britain, left her out of sight, greatly surpassing her even in iron and steel exports. John Bull, who professed to love the bracing breezes of competition which blew through his open door, has found them of late icy as Antarctic blizzards. The remedy is simple: shut it! All other nations, without exception, and his own Dominions oversea, keep their doors open, shut, or ajar, just as suits their own comfort and convenience. It is not *laissez-faire* practice by any means, but it is rational and it works unexceptionably well. Each a master in his own house, the brethren cling affectionately together, the reverse of what *laissez-faire* economists prophesied and hoped. All of these brethren are resolved to exclude the foreign scheming monopolist, as they are resolved now and hereafter to fight in phalanx the common enemy whencesoever he may come. Bismarck in 1879, or shortly before, in commending his policy, said that Great Britain would stick to her free-import *régime* for fifty years, say 1929, but he did not foresee the Great War.

Reform of Patent Laws.

German companies domiciled in Germany, in association with companies registered in England under German or other names, use our law courts to fight purely English concerns so as to restrain them from certain manufacturing methods. That is the outcome of *laissez-faire.* With our eyes open we grant a monopoly to foreign foes (commonly called "enemy aliens" in utter disregard of grammar), and thus encourage boundless energy in attacking our own industrials. Firstly, that procedure damages the national and Imperial interests, for a suit may and does relate to articles of urgent necessity in war and useful in peace. Next, it gravely affects artisans, and, finally, the work and profits of industrials. German companies, with British branches constituting juristic persons according to the sweetly attractive fiction, may not even introduce German capital, they may simply borrow British money to fight Britons. Everybody knows that, but there is no representative body to attack the evil and with clamant voice to demand its suppression in the name of common-sense.

German and other foreigners, inimical or not, readily obtain British agents in any part of the Empire, with capital of the agents' own and what they can borrow, to distribute the foreigners' manufactures. Freed from all local taxation they earn profits for the foreigner, often under harsh and arduous conditions whilst subject to displacement, in violent and even deadly antagonism to the British producer and employer of talents and labour. Chambers of Commerce cannot interfere with that kind of thing without compromising their own *raison d'être.* But manufacturers' associations exist primarily to defend British industry and to help against foreign aggression. The functions are absolutely opposed, so that no man,

nor corporation, can serve two masters—*Aut unum sustinebit, aut alterum contemnet.* Our British press is splendidly national, and rests its claims for changes upon ultimate demonstration; but where at present is the public body to supply it with authenticated facts as to the nation's producers, their interests, their dangers and their hopes? When there is a public wrong to rectify, or a national gain to be made as against vested foreign interests, the story must be oft repeated by the Press ere the needed change be effected.

Imperial Free Trade Impracticable.

The Oversea Dominions never have proposed, and are certain not to propose, free interchange within the Empire. Each is striving earnestly and loyally to develop to the utmost its own resources, whilst favouring the Motherland in such manner as the several Parliaments consider practical. Each Dominion seeks to diversify and to expand its industries with due regard to local conditions and probabilities. Thus where it suits Canada to establish textile industries in cotton and linen, it is highly improbable that Australia, New Zealand and South Africa will introduce them. Assuredly each dominion will decide such points for itself. We have not space to extend the illustrations, but that just adduced may suffice. And here I wish to submit a proposal with a view to the development and increased solidarity of Imperial industry after the War.

A Movement for Solidarity.

In Canada and in Australia are provincial societies of industrials, usually incorporated, denominated in the former country Manufacturers' Associations, and in the latter Chambers of Manufacture. In each Dominion there is a central body, forming a union of the several provincial societies, which deals with matters of federal interest. It affords an opportunity to the delegates to consider and to make recommendations upon national matters as persons skilled in their own sphere and representative of important national interests. In Australia, at least, industrial courts settle the one question of difference between employers and employed, the payment and conditions of labour. That settled, all the interests of the people engaged are at one, consequently in industrial matters manufacturers' associations represent large sections of the community—in Canada 520,000 employees, in Australia 340,000, besides much larger numbers dependent upon these.

My proposal is that there should be formed in Great Britain, in like manner, manufacturers' associations solely to represent producing interests, apart from those of distributors of foreign-made goods. As things stand in Great Britain industrial interests are affected, and possibly on occasion overborne by the purely commercial. Importers and manufacturers are inextricably mixed in the Chambers of Commerce, although there are, curiously enough and in contradiction to their own general principle, Chambers of Commerce in purely manufacturing towns and districts. Even with these the representation cannot be so clear and authoritative as if they were directly and solely chambers of manufacture representing the national interests of producers. A merchant with half a dozen clerks—I know of cases—supplies in Great Britain foreign-made articles in competition with British manufacturers of similar goods. With interests in complete antagonism, both sets of people are included in chambers of commerce. Yet in replacing the goods brought from abroad we might well provide incomes for British workers to the number of hundreds of thousands. Even the merchants' six clerks are countervailed, because still more English clerks would be required to keep account of the English manufactures. Surely, then, it is desirable that those who do employ English artisans should join in distinctive associations to consult over their common national interests and to make recommendations to the authorities tending to the wealth, strength and progress of the nation.

At present, the Manufacturers' Associations of Canada and the Chambers of Manufacture of Australasia are excluded from Congresses of Chambers of Commerce. It is altogether right and proper that they should be so excluded, because the interests represented by associations primarily of importing traders are those of a comparatively small number in any British community. On the contrary, citizens represented in their industrial life by Manufacturers' Associations are numerically many hundredfold greater. Moreover, in respect of national defence and stability, they are incomparably more important. In Australia, pastoralists, farmers, mine-owners, ship-owners, manufacturers, merchants and retail traders have, each separately, their own consultative and representative body, well organised. The resultant benefit to the entire community does not require explanation.

Industrials are Imperialists.

It would follow upon the formation, however small at first, of manufacturers' associations in Great Britain, that their colleagues and brethren from overseas will quickly desire connection with them. Their aim is quite sure to be Imperial strength and development of British industry all over the world. It cannot be denied that with the merchant it is largely *ubi bene ibi patria*, but the industrial is rooted to the soil. From his very circumstances and in point of observed fact, the manufacturer is profoundly and energetically nationalistic; he has travelled widely and is compelled to keep himself *au courant* with the work of the world in his line. His view of mankind goes beyond his till. He does not hold it to be the chief end and aim to buy cheap and sell dear. He does not admit the glory or the wisdom from the national view-point of buying in the cheapest market and selling in the dearest. He holds it to be lofty sagacity in the national legislature to apply itself in all ways to see that the people at home get incomes, have the local field for industry held open for them and preserved to them, that the national prosperity be broad-based upon good wages and reasonable conditions to the exclusion of "sweated" goods from abroad. He sees that other countries are rid of grinding poverty, and holds that Great Britain can get rid of it too without expropriation of anybody.

Fair Trade is Bonny Trade.

An eminent exponent of *laissez-faire* and of a twelve-hour day for children, to whom statues have been erected in England, declared that he would not oppose the practice of adulteration of goods because it was a form of competition. Unquestionably it is so. Having been twice president of the largest Chamber of Manufactures in Australia, as also twice the president of the Associated Chambers, occupying the chair at the formation of the latter body, I am able to speak for the men that I hold so much in honour. Without a dissentient voice they voted for, year by year, and urged upon the Government, preference to Great Britain. They have upon all occasions, and during a long series of years, declared for absolute purity in the official food-standards. They have declared for truthful labels. They have passed resolutions repeatedly, and presented them to the ministries of the day desiring the prohibition of false and fraudulent medicines and alleged cures. Action was taken by the Legislature for the benefit of the innocent and the ignorant, so that numerous fraudulent drugs are prohibited in Australia which are still actively sold and advertised in Great Britain. True, a Select Committee of the House of Commons has recently condemned these very drugs, following a report presented in Australia, but the committee's report has been indefinitely shelved. In the face of strong representations from important and independent public bodies, with a large block of votes at their back, or in the very near distance, legislators are seldom supine. You cannot expect traders to take action, because the drug-packers themselves have a special section in Chambers of Commerce to protect their very solid interests against adverse legislative action.

Family Education.

Manufacturers exchange information as to processes, methods, improvement of installations and novelties in practice. Especially our American and Canadian friends are remarkably broad-minded and handsome in that regard. On the other hand, I have frequently read notices in German trade papers warning their constituents that such-and-such a foreigner, naming him, was in Germany, might be seeking information, and to be sure to close their factories against him. But the Germans were, all the same, apt and ardent students whilst accepting American hospitality. The greater the intercourse and fraternal meeting by industrials from all parts of the Empire the greater will be the solidarity. Fields of operation will be discussed, whilst always and everywhere there will be devised schemes and plans for Imperial advancement along the solid line of industry.

I have spoken chiefly of Australia and Canada as being prominent examples of oversea Dominions, but with no intent of ignoring the others. In the vast Indian Empire, in our immense and continuous African Empire as the war will leave it, we have to prepare for mighty development. How can we do better than place the unofficial initiative in practical and practised hands? If we had a Manufacturers' Association of the British Empire it would be active, sound and conservative in the best sense. You want for that cool and able men, not starry brilliants. But they must be unafraid of shibboleths, men who will use all honourable means that can be found, without regard to party or the feelings and ambitions of party leaders.

Harvests of Empire.

Long ago it was said of the Spanish Empire that upon it the sun never set. We have become

heritors of the epigram, but more wonderful is the fact that in the *orbis terrarum* of the British nation there is a ceaseless round of harvests. When shearing of wool ends in one Dominion, it is beginning in another. When apples are ruddy in the orchards of New Norfolk, the air is heavy with perfume of the blossoms in Quebec. In greater or less altitudes, in higher or lower latitudes, all round the planet, there is such gradation of the seasons that gathering of crops, the same kind of crops, proceeds uninterruptedly from January to December. In Greater Britain there is diversity of land and climate, but in the minds and hearts of the citizens a family likeness. As it is better expressed in the exquisite lines of Ovid :—

Facies non omnibus una,
Nec diversa tamen, qualem decet esse sororum.

DISCUSSION.

The Chairman (George R. Parkin, C.M.G., LL.D., D.C.L.), in opening the discussion, said he did not think anything could be more certain than that when the war was over we should be living in a world which was new in a very great many particulars—new in its outlook, new in the relations of nations, and new in the relations of individuals—and perhaps there was no sphere in which that would be more true than in that of commerce. Anyone who had seen the marvellous progress which Germany had made, in the last twenty years particularly, must have been struck by one great fact, namely, that in that country's industrial and commercial development there had been a close association of Government, of finance, and of private and individual effort. Each had played into the hands of the other, and he could not help thinking that it was a great lesson to British people, who had entirely relied and leant upon private effort to the exclusion of that collaboration which the Germans had devised between those other two great forces to which he had just referred. He would not touch upon the argument that there should be a mutual preference in every part of the Empire for the products of every other part, but he desired to point out that after the war was over the different parts of the British Empire would have, and indeed were already having, secured to them, a preference greater perhaps than they could have obtained under ordinary trade conditions. It was impossible for him to think, after the Songs of Hate which we heard from the Germans, that in the future German commercial men would be able to manage their business in English-speaking countries with the same ease that they had heretofore done. Therefore there were going to be new and vast openings for British industry; and more than that. All the nations of the world were going to emerge from the conflict exhausted, and never in history would it be so necessary to have mutual consideration existing in a great Empire like the British Empire between the Government, financiers, and private individuals. In every matter the nations would have to face the work of building up new business. In such a condition of affairs, all prejudices which might be held by people in certain directions as to how trade should be conducted, should be swept aside, and the matter approached with open mind. When the war was over there would have to be a great consultation between the public men of the British Empire—not only statesmen, but business men, manufacturers, traders, and shipowners. He had said that we were going to be exhausted. That would depend somewhat upon ourselves. It would be remembered that when France was crushed in the war of 1870, and when she had to pay £200,000,000, apparently every Frenchman determined to live on as little as he could, and tried to produce everything he could to sell to somebody else, with the result that within a few years France was a richer nation than she had ever been before. That course was open to us also, and we must not fall back into our *laissez-faire* habit. There would have to be a clean and a clear consideration of all great industrial questions. The economy which was being practised in the country to-day would have to continue after the war. He believed that the huge sums which were being subscribed for philanthropic purposes at the present time were really saved by the economy of the people in their ordinary living. There was one more remark he desired to make. Another curious condition would emerge as the result of the conflict. In addition to being the greatest naval power in the world, we were also going, much against our wish, to be a great military power, with the result that we should have an increased world-wide influence. That was going to lay upon the Empire great responsibilities. There would be new opportunities, new fields for work, and we should have new moral and material weight in every corner of the world; and in order to be able to discharge those responsibilities aright, and to maintain the strength which was given us in that way, we should have to take new lines. The British Empire was finding itself to-day as it never found itself before. It had been found that the various parts of the Empire could work together as a united force all round the world, each one doing its own share with enthusiasm, extreme willingness and spontaneity. Our statesmen would not be doing their duty if they did not organise those vast forces of enthusiasm which had been put in motion. Men of great imagination and great power, in commerce as in politics, were required to grapple with the question. In that way, in addition to the Empire emerging from the struggle a greater naval and military power, its industry and commerce would have a still greater future, and would be given a security greater than it had ever had before.

The Hon. Sir John McCall, M.D. (Agent-General for Tasmania), said the paper, which

reminded the audience of all the work which had been done by our forefathers in establishing industries and in giving to the world a culture which it did not possess before, certainly served as a tonic, and it was well that people should be reminded that the position of the world was largely due to the work of Britishers; and although some of the fruits of that work might have been stolen from us by the astuteness or the thieving propensities of our enemy, it should always be remembered that what Britishers made in the first place could be taken back. The Colonies had always endeavoured to give preference to the manufacturers of Great Britain, but that preference was taken away by the acts of some people in this country. In some cases English ships carried manufactured goods to the Dominions from Germany at a considerably less cost than freights of English manufactured goods. By so doing they were robbing the manufacturers of Great Britain of the benefits of that preference which the people of the Dominions were so anxious to extend to them. There was a great deal to be done in the matter, but it could not be settled at a public meeting; it could only be discussed behind closed doors by selected men. He believed it was absolutely essential for the future of the Empire that at the close of the war there should not only be a formation of Imperial Chambers of Manufacturers, but also a gathering of Imperial statesmen from every part of the Dominions in order to decide what was the best thing to be done for the future of the Empire and its permanency.

Sir Boverton Redwood, Bart., D.Sc., F.R.S.E., said there was one feature of the subject to which recently he had had occasion to pay some little attention, and that was the present position of the zinc-lead question, and he felt very strongly that some decisive action was in the highest degree necessary. He hoped due attention would be paid, by those who had the opportunity of dealing with that question authoritatively at the present time, to the statements which had fallen from the author. Probably the statement was not exaggerated that in respect of Australasia that question was of greater importance than was the aniline dye industry in respect to this country. He would go further, and say that whatever might be the importance of that question to Australia, it was in a sense of even greater importance to us as a matter of principle that we should take advantage of the present opportunity of helping Australia to take, or of taking ourselves, that which never ought to have gone to Germany. Therefore in that particular matter there was a direct responsibility resting upon those in this country who were dealing with it.

The Hon. J. G. Jenkins (late Agent-General for South Australia) said he appreciated everything the author had said, although he did not entirely agree with all his conclusions. With reference to the mineral industry of Australia, the Germans had something in their minds, when they arranged the contracts with Broken Hill and all the other mines for the supply of metal to the German companies. Those contracts contained a clause specifying that they should be continued even if suspended during war—a provision that no English company, as far as he knew, had ever put into a contract at all. He was not sure, but he did not think the Commonwealth Government had yet passed legislation actually to nullify the existing contracts, but he understood they were prepared to do that on the understanding that something would be done to furnish a market in this country for the purchase of the outputs of those mines. It was well known that when war was declared, and the output of the mines stopped, 20,000 people were immediately thrown out of employment, and it was only after a reorganisation that work was resumed. What did that mean? It meant that for years Australia had sent hundreds of thousands of pounds' worth of minerals to Germany; that the Germans had employed tens of thousands of men to turn that metal into products, and that then they had supplied them to various parts of the British Empire. Really Australia had furnished the raw material to Germany for that country to employ its labour and increase its wealth. He thoroughly agreed with the suggestion that there should be a convention of statesmen and business men held after the war to discuss all vital matters connected with the trade and commerce of the Empire.

Sir Edward Durand, Bt., C.B., said as far as he could see, Great Britain had never troubled herself about her trade abroad. It was also quite impossible, or had been hitherto, to get financial aid from the Government in the starting of any new process or business, whereas with Germany it was quite the contrary.

Mr. J. M. Fells said the paper had interested him particularly because it dealt, amongst other things, with a science of which he had been a humble student, namely, that of economics. The author had quoted in that connection a significant passage by Abraham Lincoln, which reflected very much the habit of mind of many people with regard to economics. The author himself was not quite of that school, because he had himself adopted the tenets of the German economists in many ways, and had practically advocated what might be called "national economics" as opposed to "general economics," or political economy. In that connection it had to be remembered that, if the national economic system were adopted, one must admit that fiscal rules and regulations were not of universal application, and that which might be a good code of fiscal regulations for Australia, with its large continent and rich minerals and great natural advantages, might not be the best for a small island like Great Britain.

The author was practically admitting the whole principle of economics when he agreed there were such things as national economics; and it had to be remembered in that connection that unless it were admitted there was such a thing as economic science, and, if the theory of foreign exchanges was ignored altogether, one was driven back to the position of a village community producing all its own things by itself, self-contained and self-satisfied —in that way all commercial and financial progress being marred and prevented.

Mr. E. T. Scammell said reference had been made several times to what would happen at the conclusion of the war. It did seem to him that steps to deal with the matters raised by the author and others should be taken not after the war, but in preparation for the close of the war, because when hostilities were concluded so many political and other difficulties would arise that some of the most important matters which had been discussed that evening would be relegated to some far distant date.

Mr. W. F. Leeson remarked that the great fact had to be faced that for forty years Germany had built up an enormous trade. He agreed with the Chairman that that had only been possible by the combination of the German manufacturer, financier and Government, and it could not be too deeply impressed upon the people of Great Britain that such a combination was needed in this country in order to capture trade.

On the motion of the Chairman a hearty vote of thanks was accorded to the author for his valuable and interesting paper.

The Author, in reply, said that Mr. Jenkins had dealt with the question of the Broken Hill Mine and how the Germans held that trade. They had obtained it by foresight in making contracts over a large number of years, and also they had certain processes of which they were not the inventors, but of which they had possession. His Free Trade friend would no doubt consider that that was perfectly right, but he personally considered it was absolutely wrong for an Empire to allow its inventions to go to outsiders, who were thus enabled to employ thousands of men, who were supported by their Governments and who took full advantage of the Free Trade system whereby their articles were carried in British ships at a lower rate than British goods were carried over a less distance. It was astonishing. Taking copper, the largest copper refinery in the British Empire was in Australia, and yet the output was controlled by Germans. It was for the Government to see that such things did not occur again. He agreed thoroughly with the suggestion that something should be done before the end of the war, which no doubt would be a time of great mental and commercial turmoil.

ENGINEERING NOTES.

Sydney Harbour Bridge.—On January 8th these columns contained an outline of the proposed Sydney bridge and city railways. Further particulars have now been received of the former structure, which will rank third in the world in importance, the Forth and Quebec bridges coming first and second. In some respects, however, the Sydney bridge surpasses them, being 170 ft. high while they are 150 ft. only. The bridge will consist of nickel steel cantilevers, supporting centre girders, also constructed of nickel steel. The anchor or shore arms are each 500 ft. long, and the harbour or cantilever arms 520 ft., while the central suspended span is 560 ft. The main piers supporting the cantilevers are placed 1,600 ft. apart, centre to centre. The total length of the steel work is 2,600 ft. Provision is made between the main girders for four lines of electric railway, and a roadway 35 ft. wide. Outside the main girders on the eastern side is a motor roadway 18 ft. wide between the handrails, and on the western side a footway 15 ft. wide. The main girders are vertical and 94 ft. 6 ins. apart. The central suspended span of the bridge will be level, with grades of 1 in 39 on either side. A headway of 170 ft. above high water is provided for the central span of the bridge, whilst a headway, not less than 156 ft., is provided over the whole fairway. The upper and lower chords are braced against the wind. The trusses of the central suspended span are 100 ft. deep between centres of chords, the chords being parallel. The depth of cantilevers at the towers is 270 ft. between chord centres. The web systems are of the Warren type throughout, all main members being inclined. Panels are subdivided, and there are minor supporting and stiffening members. The method of erection will be to construct the anchor arms on false work after the main and anchor piers are completed, then build out the cantilever arms, making direct use of the anchor arms for support. The suspended span would also be built out by the cantilever method, the construction from both sides meeting at the centre of the bridge. On completing the suspended span, the cantilever connections will be freed, so that the span will act as an independent truss supported on the ends of the cantilevers. The floor systems, with the exception of the main cross girders, are to be constructed of carbon steel. This was found to be desirable in order to minimise secondary trusses due to the deflection of the various girders, etc. The higher unit stresses of nickel steel would cause greater deflections than would be the case for carbon steel members, other things being equal. Since the webs, etc., of most of the girders are decided by minimum allowable thickness of metal rather than from stress considerations, the use of nickel steel would in this case be an unwarranted expense. The floor, owing to the magnitude of the bridge and its variety, is very important. The railway tracks are carried on three stringers throughout the bridge. An intermediate

system of floor beams is placed upon the stringers, and on these floor beams rest built troughs which carry the rails. The rails are fastened to longitudinal wooden sleepers inside these troughs. The upper flanges of the troughs are braced at appropriate intervals, and there is a general covering of ½ in. steel plate over the whole railway tracks. The flooring of the main roadway will consist of wood blocks, or rock asphalt, carried on coke concrete, having a minimum thickness of three inches above buckle plates. The buckle plates are carried on rolled joists placed on longitudinal plate girder stringers. The motor roadway is designed for lighter motor traffic, and has a wearing surface of one inch of rock asphalt carried on coke concrete with buckle plates, as in the main roadway. The footway also has buckle plate flooring, with a wearing surface of one inch of rock asphalt, there being a filling of coke concrete, levelled with the top of the buckled plates.

A Searchlight of Moderate Range.—The introduction of the concentrated filament incandescent lamp of the gas-filled type is ushering in a new era in the field of reflector lighting. It is well known that the nearer a light source approximates to a point at the focus of a lens or reflecting mirror, the more powerful become the coalescing rays along the axis, and in some of the latest electric incandescent headlights and small searchlights for railway, military and industrial service, this principle is taken advantage of with remarkable effect. With the expenditure of what are in reality only trifling amounts of electrical energy, properly equipped lamps are now coming from the manufacturers which are likely to set a new standard in special lighting, and it behoves the contractor seeking to illuminate construction jobs at night economically along concentrated lines, to look into the developments in this field.

The Development of the Submarine.—Though experiments in the building of submarine vessels go back many years, dating from 1620, their actual appearance as ships of war is only of recent date. Within the last few years the development of this branch of the service has been rapid, and France particularly has added many submarines to her navy. The British Admiralty first decided on submarines in 1900 when Lord Goschen was the First Lord. After carefully surveying the position, the Admiralty sent to America and decided that the type of submarine invented by Holland was the best. The inventions were purchased, five Holland boats were built, and since that time improvement has followed improvement, but the most noteworthy feature of recent years has been the successful development of the Diesel oil engine, with a corresponding increase in the size of the vessels.

High-speed Electric Locomotives.—During the year, sixteen high speed electric locomotives have been placed in the main line passenger service of the New York Central Railroad. This type of locomotive, states *The Railway News*, is claimed to be the most powerful electric passenger motor thus far constructed, and is capable of continuously hauling a train of fourteen steel Pullman cars at a sustained speed of sixty miles per hour. With lighter trains the maximum speed of these locomotives is eighty-five miles per hour. The electrical features of these locomotives are generally the same as in the original ones first operated by the company eight years ago. The new locomotives weigh 132 tons, and the great increase in capacity, compared with the comparatively slight increase in weight, is due to the fact that motors have also been placed on the axles of the leading and trailing bogie truck wheels, thus avoiding all dead weight, all the wheels being driving wheels, and the entire weight of the locomotive being thereby available for producing tractive effort or drawbar pull. Further westward, on the Chicago, Milwaukee and Saint Paul Railway, a contract has been let for the electrification of 113 miles of track, presenting several points of interest. According to *Electrical Engineering*, overhead conductors are to be used with a direct current contact line pressure of 3,000 volts, with flexible catenary construction and pantagraph collectors. Power will be supplied to the sub-stations —which will be equipped with synchronous motor generators—at 110,000 volts three-phase 60 cycles, from water-power stations of the Montana Power Company. Very large and powerful locomotives will be used, constructed in two permanently coupled units, each having eight driving wheels and a four-wheeled bogie at the ends. The driving axles are arranged in pairs upon a series of four articulated trucks, two under the main frame of each unit. Each driving axle is twin geared to a 375 horse-power—continuous rating - motor, and the motors are permanently connected in pairs in series. The whole vehicle weighs 260 tons, of which 200 tons are available for adhesion, and the starting drawbar pull is 89,000 lbs. The passenger locomotives will haul an 800-ton train at 60 miles per hour on the level, and the goods locomotives will haul a 2,500-ton train up a one per cent. grade at 16 miles per hour. The control provides for regenerative braking. The plant and locomotives are being supplied by the General Electric Company, of America.

OBITUARY.

William Ewing.—The death of Mr. William Ewing, of the Mains, Giffnock, took place at Bournemouth, on January 9th, at the age of sixty-three.

Mr. Ewing was the second son of the late Mr. William Ewing, silk manufacturer, of Glasgow, and was educated in Glasgow and in France. In 1876 he founded the firm of Messrs. William Ewing & Co., Ltd., of Glasgow. He was also for

many years secretary, and subsequently a director of the African Lakes Corporation, Ltd. He took a deep interest in African affairs. In 1885 he attended the Berlin Conference on the partition of Africa in the interests of Nyasaland, and subsequently interviewed King Leopold with regard to developments in East Africa; and at the time of the Arab aggression in Nyasaland in 1891, he took a leading part in arranging for supplies to carry on military operations. He was present at the first conference of the directors of the African Lakes Corporation with Mr. Cecil Rhodes, and had a great deal to do with the extension of British South African rule over the territories north of the Zambesi.

Apart from his business activities, Mr. Ewing devoted a great deal of time and energy to scientific and charitable work. He served on the council of the Royal Scottish Geographical Society, and he was an active member of the Central Dispensary, and a director of the Anderson College Medical School. He was also honorary treasurer of the United Free Church College Student's Book Scheme, and of the Barotsiland Mission in South Africa. The restoration of Iona Cathedral was due in no small measure to his personal efforts.

He was elected a member of the Royal Society of Arts in 1902.

NOTES ON BOOKS.

INDUSTRIAL HISTORY OF MODERN ENGLAND. By G. H. Perris. London: Kegan Paul. 1914.

In his introduction the author says that his purpose has been "to outline the facts and to interpret the spirit of the economic history of Great Britain in the last hundred and fifty years." This purpose he has certainly carried out, for he has been content with a mere summary of the facts, while he has devoted a great deal of care and skill to an elaborate exposition of what he considers to have been the spirit which has animated and guided industrial progress in England during the last century and a half. Mr. Perris's views may not unfairly be summarised as those of Arnold Toynbee brought down to date and developed in accordance with the teaching of Henry George. Many of the admirers of the gifted author of "The Industrial Revolution" must have wished that a longer life had been granted to him, since the experience of advancing years might have led him to take perhaps a wider—a less one-sided—view of the subject which he treated with such brilliant insight. His followers have for the most part, clever as many of them are, shown even less capacity than Toynbee to realise that great social problems are not best treated by violent advocacy of one set of doctrines and violent abuse of all others. This, of course, is about as true of one party as of another, though the reformers, the iconoclasts, the pullers-down, are of necessity somewhat more violent than those who are more satisfied with existing conditions, more anxious to preserve than to destroy. The ancient Aristotelian ideal of moderation (*σωφρυσύνη*) is out of date, and so is Plato's advice, "*τὸ μέσον αἱρεῖσθαι καὶ φεύγειν τὰ ὑπερβάλλοντα ἑκατέρωσε.*"* Nobody sets any store on "the mean" nowadays, for salvation is only to be found in the extreme.

Mr. Perris is no friend for moderation. He is a strenuous advocate of the views of Toynbee, Henry George (with whose views, by the way, Toynbee was not in accord), William Morris, and the Fabian Society, and says as much in his introduction. The discussion of those views would lead into stormy regions. It may suffice to say that Mr. Perris states the opinions to which he has been led with much cleverness, and with commendable fairness. Whether his readers agree with him or not, it is a distinct advantage to all students of the subjects to have one side of the case stated by so strenuous an advocate. Mr. Perris has evidently studied the history of invention, for his facts seem to be stated correctly, though only the barest summary is given, and it is the social and political aspect of his subject which really attracts him. The contents of the book may be appreciated from his own (or his publisher's) summary:—"Three chapters are devoted to the period before 1832, when the influence of the economists may be said to have commenced. The subjects dealt with in the subsequent chapters include, among others, the First Factory Acts—The New Poor Law—The Chartists — Employment and Education — The Completion of Free Trade — The Trade Union Compromise—The Collapse of Agriculture—The Sweating System—Population and Wealth—Unemployment—The Minimum Wage—Invention in Manufacture, etc." The last chapter is entitled the "New Age," and of it it may suffice to say that it was obviously written before the war.

THE CONDUCT OF AND PROCEDURE AT PUBLIC AND COMPANY MEETINGS. Third (Revised and Enlarged) Edition. By Albert Crew. London: Jordan & Sons, Ltd.

The British public are so much attached to public meetings that the majority of them have a general and hazy notion of the lines on which they should be conducted, and so long as a meeting runs smoothly and harmoniously such a notion is generally sufficient for practical purposes. But when amendments begin to be moved, and that mysterious entity, "the previous question," is hinted at, many a worthy chairman, who has not made a special study of procedure, is apt to feel the ground slipping from under his feet. There is, then, a need for a compact manual such as Mr. Crew's volume, and the fact that it has now reached a third edition proves that its value has been appreciated. The author deals very simply and thoroughly with the whole question of the conduct of public meetings, from the methods of summoning them to the various complicated questions that may arise at meetings of shareholders.

* Plato, Republic, 619 A. "To choose the mean and shun excess on either side."

British Journal Photographic Almanac, 1915. (Fifty-fourth issue.) Edited by George E. Brown, F.I.C. 1,068 pages. London: Greenwood & Co.

This bulky volume makes its appearance a little later than usual this year, affected, no doubt, by the cause which upsets all our arrangements. But it is as complete and useful as ever, and will be welcomed as usual by the numerous professionals and amateurs who regard it as their photographic Bible, the compendious directory to which they turn for all general information. The two principal articles are "Methods of Enlarging," by the editor, and "Photography with the Microscope," by Dr. Duncan Reid. Besides these there is the usual chronicle of photographic events, descriptions of the year's inventions, with formulæ, tables, lists, and the innumerable odd bits of information likely to be wanted by photographers. More than half the book is made up of advertisements, and this half is quite as useful as the other, for it provides a really valuable directory of photographic dealers of every sort. As a mere matter of curiosity it may be mentioned that the titlepage is to be found in the middle of the book—on page 351, as a matter of fact—if anybody wishes to consult it.

GENERAL NOTES.

Bank Gold Reserves.—Speaking at the general meeting of the London City and Midland Bank last week, Sir Edward Holden stated that the bank held, as a reserve, the sum of 8 millions in gold in its own vaults. In case of necessity, he declared, they would have no hesitation in placing their gold at the disposal of the Bank of England. This might be taken as his answer to the other joint-stock banks which have declined to follow his example in stating the amount they hold, and which have pleaded that it was more patriotic at this juncture to keep their reserve at the Bank of England. During the crisis the London City and Midland voluntarily sent to the Bank of England an additional 2½ millions in newly-coined sovereigns. In his opinion there must be in the hands of the other joint-stock banks at least 50 millions in gold, and he is unable to understand their hesitation to show it in their balance-sheets. Another point of interest was his reference to the rumours last August associating his bank in particular with the complaint made by Mr. Lloyd George that some bankers were not doing their duty in financing the trading community. Sir Edward was able to produce a letter from Lord Reading assuring him that no allusion had been intended to the London City and Midland Bank, and to cite the instructions given to all its branches to be liberal in meeting every legitimate demand for advances.

African Wild Beeswax.—The trade in wild beeswax is constantly increasing in most of the African colonies, especially Gambia, Gold Coast, Nigeria, Angola, Sudan, Uganda, British East Africa, German East Africa, and Mozambique. A few years ago the exports of wax from these countries were almost insignificant, but now (according to M. E. Michel, the author of an article on this subject which appears in the *Bulletin Agricole du Congo Belge*) it amounts to thousands of tons. Wax occupies the third place in the export trade of Angola, which exports every year 600 or 700 tons of wax, while Mozambique exports about 100 tons, and Portuguese Guinea 50 tons. In 1911 German East Africa exported over 800,000 lbs., of the value of £40,000. The wild wax, when well purified, is comparable to European wax.

Groynes and Sea Walls.—The *Surveyor* of January 29th contains an interesting article upon this subject by Mr. A. T. Walmisley, who read a paper on the port of Dover before the Society a few years ago, and who has had great experience in dealing with works for the prevention of shore erosion. The secret of successful work, he says, is to connect groynes at the top end with a sea wall, to carry them well out into low water, to construct them only sufficiently high to retain the beach and not to obstruct the rush of water over the beach, and to provide them with an inclination of top edge parallel to the storm angle of the beach, which, upon the south coast, is known to be 1 in 10. They should be placed, approximately, at an angle of 95° to the flood tide, or at 85° from a shore, running parallel thereto, and at a distance apart equal to the distance of low-water mark from the upper sea wall at their top end. Groynes placed at angles more acute with the shore may secure the beach from scour on their lee side, but they assist the run of the sea in removal of the shingle on their weather side, as they do not afford "pocketing" for the beach. The article is illustrated with some valuable elevations and plans.

Aircraft for the Italian Army.—The French journal, *La Liberté*, states that some experiments with a new powerful type of aeroplane, which it terms a "super avion," have been made at the military aerodrome at Vizzola-Ticino (Lombardy), and have given satisfactory results. These trials have been conducted with a certain amount of secrecy. The new machine, the design of an Italian engineer, Signor Caproni, is provided with three independent rotary motors of 100 h.p. each. Carrying a weight of 500 kilograms (nearly half a ton), it rose to an altitude of 2,000 metres (6,560 feet) in twenty minutes. With a load of 1½ tons it attained a speed of 120 kilometres (75 miles) per hour. It is capable of remaining in the air for twenty-five hours. It carries a quick-firing gun. The machine is protected with armour. Two other craft of a similar type are being constructed, one of 600 h.p. and the other of 1,000 h.p. They will be heavily armed.

Water Hyacinth as a Fibre Producer in Indo-China.—As a result of the spread of the water hyacinth (*Eichorina crassipes*) in the waters of Cambodia and other parts of Indo-China, there has been an investigation in that colony as to possible uses the plants could be put to as a means of clearing the rivers for navigation. In connection with the discussion a French professor has announced to the Chamber of Commerce at Saigon the results of experiments he has made with the plant as a fibre producer. He has extracted the fibre from the stalk by means of a Ducheman machine, and finds that after drying, preferably by gradual process, it can be made into serviceable rope and twine as well as coarse thread suitable for matting and sail cloth, and its use in Indo-China particularly is possible in bags for rice and other grain exports in place of the jute bags now imported. On a native loom it affords a strong flexible cloth of about the same quality as jute. The fibre takes dye readily and has high tenacity. Its weight is about the same as that of jute, but can be reduced by treatment with chrome alum, which makes the product waterproof.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock (except where otherwise announced):—

February 10.—F. Vincent Brooks, "British Lithography in 1915." Carmichael Thomas, Chairman of the *Graphic* and *Daily Graphic*, will preside.

February 17.—Arthur Wilcock, "The Decorative Textile Industries and the Designer's Relation thereto." Sir Charles Waldstein, Litt.D., Ph.D., will preside.

February 24.—W. J. Ashley, M.A., M.Com., Ph.D., Professor of Commerce in the University of Birmingham, "The Economics of the War." The Right Hon. Sir George Houston Reid, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, will preside.

March 3, at 4.30 p.m.—William Poel, "Shakespeare's Profession." Sir Squire Bancroft will preside.

March 10.—J. W. Gordon, "Patent Law Reform and the War."

March 17.—H. M. Thornton, "The Industrial Uses of Coal Gas."

March 24, at 4.30 p.m.—Lady Lugard, "The Work of the War Refugees' Committee."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

February 11.—Captain Sir George Duff Dunbar, Bt., I.A., "Tribes of the Brahmaputra Valley." Lieut.-Colonel Sir Francis Younghusband, K.C.I.E., LL.D., D.Sc., will preside.

March 18.—Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army."

April 15.—Perceval Landon, "Basra and the Shatt-ul-Arab."

May 13.—M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March 2.—David Lindsay (of the Elder Scientific Exploration Expedition, etc.), "The Northern Territory of Australia: Past, Present, and Future."

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced:—

Thomas Worthington, "The Work of the Commercial Intelligence Branch of the Board of Trade."

T. Thorne Baker, "The Industrial Uses of Radium."

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. Hulme, "Patent Law."

D. Y. Cameron, A.R.A., R.E., "Etching."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

A. S. E. Ackermann, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., "On an Economical and Smokeless Grate, and on the Measurement of the Efficiency of Open Grates."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

M. H. Baillie Scott, "House Building—Past and Present." Three Lectures.
March 15, 22, 29.

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.
April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evenings, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 15.—*Petrol.* Its production and properties — The composition and grades of petrol — Transportation, storage, and distribution — The dangers of petrol — Calorific value, and how far it is a basis for comparison— The properties essential in a good motor fuel— Vapour tension and fractionation as indicators of the value of a petrol—Supply and demand.

LECTURE II.—FEBRUARY 22.—*Petrol Substitutes.* (*a*) Definite; compounds — Benzol and alcohol. (*b*) Mixtures—How far mixtures of heavier grades of petroleum with spirit can be used. (*c*) The "cracking" of heavier fractions of petroleum into spirit—The researches upon which such processes are based, and their teaching.

LECTURE III.—MARCH 1.—"*Cracked*" *Spirits.* The effect of degree of temperature used—The use of water or steam—Surface action and its supposed effect—Processes in use—The utilisation of gases in solution to increase vapour tension—The steam engine *versus* the internal-combustion engine for motor traction—Conclusions.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 8...Engineers, Cleveland Institution of, Corporation-road, Middlesbrough, 7.30 p.m.

Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. H. Boot, "The Production and Use of Steam in Breweries."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Discussion on Messrs. J. G. Head and J. Bury's papers on "The Report of the Land Enquiry Committee on Urban Land Tenure."

Geographical Society, Burlington - gardens, W., 8.30 p.m. Colonel P. Molesworth Sykes, "A Seventh Journey in Persia."

TUESDAY, FEBRUARY 9...Electrical Engineers, Institution of (Scottish Section), 207, Bath-street, Glasgow, 8 p.m. Professor M. Maclean and Messrs. D. J. MacKellar and R. S. Begg, "Distribution and Rise of Temperature in Field Coils."

(Manchester Section.) Liverpool, 7.30 p.m. Professor E. W. Marchant, "Conditions affecting the Variations in Strength of Wireless Signals."

Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Professor A. J. Herbertson, "Some Sociological Geographical Problems of the War."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Professor A. A. Macdonell, "The Development of Early Hindu Iconography."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Muscle in the Service of Nerve." (Lecture III.)

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. Mr. F. D. Evans, "Engineering Operations for the Prevention of Malaria."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. C. A. Klein, "Some Chemical and Physical Aspects of the Decorator's Art."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Annual General Meeting.

Zoological Society, Regent's-park, N.W., 8.30 p.m. 1. Mr. G. Aylmer, "Exhibition of Skins of Mammals from Sierra Leone." 2. Mr. E. Heron-Allen, "Exhibitions of Skiagraphs of Foraminifera." 3. Mr. H. G. Plimmer, "Reports on the Deaths which occurred in the Zoological Gardens during 1914." 4. Mr. E. G. Boulenger, "On a Colubrid Snake (*Xenodon*) with a vertically movable Maxillary Bone." 5. Dr. W. Nicoll, "A new Liver-Fluke from the Kestrel."

Pharmaceutical Society, 17, Bloomsbury - square, W.C., 8 p.m. 1. Professor H. Llewellyn Smith, "Acetylsalicylic Acid." 2. Professor H. G. Greenish and Dr. Alan E. Beesley, "Discolouration of Sodium Salicylate in solution by Alkalines."

WEDNESDAY, FEBRUARY 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. Vincent Brooks, "British Lithography in 1915."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7.30 p.m. Mr. N. Shuttleworth, "Polyphase Commutator Machines."

(Yorkshire Section.) Bradford, 7 p.m. Professor E. W. Marchant, "Conditions affecting the Variations in Strength of Wireless Signals."

Biblical Archaeology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Dr. Gaster, "Samaritan Phylacteries and Amulets."

Literature, Royal Society of, 20, Hanover-square, W., 5 p.m. Professor M. A. Gerothwohl, Lecture on "Comparative Literature."

THURSDAY, FEBRUARY 11 ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Captain Sir G. D. Dunbar, "Tribes of the Brahmaputra Valley."

Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. H. H. Stockfeld, "The New Reform System of Ice Manufacture and Refrigeration."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

African Society, Whitehall Rooms, Whitehall-place, S.W., 5 p.m. Mr. H. Birchenough, "Some Effects of the War upon British and German Trade in Africa."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. P. Chalmers Mitchell, "Zoological Studies. War and Evolution — Nations as Species." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. J. G. Broodbank, "The Port of London and its Docks."

Optical Society, at the Chemical Society, Burlington House, W., 7.30 p.m. 1. Annual General Meeting, 2. Discussion on "Sight Testing."

Child Study Society, 90, Buckingham Palace-road, S.W., 6 p.m. Dr. C. W. Kimmins, "With the British Association in Australia."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Professor E. W. Marchant, "Conditions affecting the Variations in Strength of Wireless Signals."

Art Workers' Guild (Junior), Queen's-square, W.C., 8 p.m. Mr. L. Weaver, "Monuments and Memorials."

University of London, University College, Gower-street, W.C., 5.30 p.m. Monsieur C. Poupeye, "Belgian Art." (Lecture IV.)

FRIDAY, FEBRUARY 12...Royal Institution, Albemarle-street, W., 9 p.m. Dr. W. S. Bruce, "Recent Advances in Oceanography."

Physical Society, Imperial College of Science, South Kensington, S.W., 8 p.m. Annual General Meeting.

SATURDAY, FEBRUARY 13...Royal Institution, Albemarle-street, W., 3 p.m. Dr. H. W. Davies, "Emergency Music." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,247. VOL. LXIII.

FRIDAY, FEBRUARY 12, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 15th, 8 p.m. (Fothergill Lecture.) PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." (Lecture I.)

WEDNESDAY, FEBRUARY 17th, 8 p.m. (Ordinary Meeting.) ARTHUR WILCOCK, "The Decorative Textile Industries, and the Designer's Relation thereto." SIR CHARLES WALDSTEIN, Litt.D., Ph.D., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, February 11th; LIEUT.-COLONEL SIR FRANCIS YOUNGHUSBAND, K.C.I.E., LL.D., D.Sc., in the chair. A paper on "The Tribes of the Brahmaputra Valley" was read by CAPTAIN SIR GEORGE DUFF DUNBAR, Bt., I.A.

The paper and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURES.

The Cantor Lectures on "The History and Practice of the Art of Printing," by R. A. PEDDIE, Librarian of the St. Bride Foundation Typographical Library, have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor and Howard Lectures which have been published separately, and are still on sale, can also be obtained on application.

EXAMINATIONS.

Two examinations in all three Stages (Advanced, Intermediate, and Elementary) will be held this year, the first in March and the second in May. The March examinations will commence on the evening of Monday, March 22nd, and continue till March 31st. The last day for receiving entries is February 22nd. The May examinations will commence on the evening of Monday, May 10th, and continue till May 19th. The last day for receiving entries is April 9th. In the County of London the Elementary Examinations only will be taken in March and the Intermediate and Advanced Stages only in May. The London County Council Education Committee will receive the entries for the examinations in the County of London not later than February 20th and March 20th respectively.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, January 21st, 1915; The RIGHT HON. SIR HERBERT MAXWELL, Bt., F.R.S., in the chair.

THE CHAIRMAN, in opening the meeting, said it was his privilege to introduce the reader of the paper, Mr. Elwes, to the audience, and he felt peculiar pleasure in doing so, because he knew the author was exceedingly competent to deal with the subject he had chosen. A man had no business to talk about anything that he did not know, and it, therefore, became important to inquire how a man was to acquire knowledge. The answer to the question would, he thought, be found in the vocabulary of the ancient Greeks. When a Greek wanted to say, "I know," he said, *οἶδα*, which was the preterite tense of the verb *εἴδω*, "I see." Therefore, when he said "I know," he

also said, "I have seen." Mr. Elwes, far travelled, had seen many things that few present could ever hope to see, and he, therefore, knew a great deal more than most of them. He would now call upon Mr. Elwes to read his paper.

The paper read was—

NEPAL.

By Henry John Elwes, F.R.S.

I must commence by saying that it is with some reluctance that I consented to give some account of a recent visit to this country, because, except from a naturalist's point of view, I can add little or nothing to what is known by those who have been there; because it is impossible to form correct opinions on a country of which such a very small part has been visited by Europeans; and, lastly, because my companion, Mr. Trevor-Battye, on whom I had relied to tell you more about the scenery, which his photographs so well illustrate, is, owing to illness, unable to be present.

Nepal is unique in this respect, that it remains, a solitary instance in the world, of a friendly country which, from political reasons alone, is inaccessible to Europeans. For, though during nearly a century our relations with its rulers have been perfectly peaceful, and latterly even cordial, and though the present ruler of Nepal is a man of European culture, speaking perfect English, and understanding English customs, politics and civilisation in a way that few Oriental rulers do, he has rigidly adhered to the policy instituted sixty years ago by the all-powerful minister, Jung Bahadur, and has maintained a system of government which may be best described as a paternal despotism founded on the religion and customs of his people. It is, therefore, impossible for Europeans even to enter Nepal unless specially invited, as we were, by the British Resident at Katmandu, Colonel Manners-Smith, V.C., or by the Maharaja Sir Chandra Shamsher Jung, G.C.B., G.C.S.I., G.C.V.O., to both of whom our most cordial thanks are due for their hospitality and kindness during our too short stay there.

Though our relations with the Nepalese Government were not at first so uniformly friendly as they have been ever since the Indian Mutiny, when Jung Bahadur came to our assistance with his army, yet we have learned that it is possible to do what has never been done by any other European Government—to live as neighbours on a frontier of over five hundred miles without any friction with an Oriental nation distinguished for the bravery and patriotism of its people. And after comparing the conditions which exist in the kingdom of to-day with the state of some parts of Bengal in recent times, I think that we can learn much from the Nepalese in the art of governing primitive mountain races. I will refer those who wish to know more of the country to Sir W. W. Hunter's "Life of Brian Hodgson" (1896), who resided in Nepal as British Resident for many years, and who was the first to make known to science a great number of its animals and birds; or to the "Imperial Gazetteer of India," Vol. XIX. (1908), where an excellent account of the country will be found. Hodgson went to Nepal as a young man in 1820, as clerk to the Resident, and only remained two years; but as his health broke down in Calcutta he returned in 1824, and in 1825 was made Assistant Resident, a post which he filled until 1833. During this time he studied the people, languages, products, and trade of the country as no one has done since; and when Sir Herbert Maddock, his chief, retired in 1833 he succeeded him as Resident. The internal feuds which went on at this time made his position a very difficult and, at one time, a dangerous one; for during a mutiny of the native troops which took place in 1840 a plot was formed to attack and destroy the Residency with its guard and inmates. But Hodgson, as brave as he was diplomatic, succeeded in holding his own during the trying period of the Afghan War, and might have remained in Nepal for many years if he could have got on with Lord Ellenborough. But in 1843 Hodgson, unable to bear any longer the treatment of that autocratic Governor-General, retired, to the great grief of the Raja and people. He then went to Darjeeling, where he lived until 1858, and spent the time entirely in scientific work relating to the languages, religions, ethnology and zoology of Nepal and Tibet, which for quality and quantity has hardly been equalled by any other member of the Indian Civil Service. He then returned to England, where he lived until 1894, in the enjoyment of the numerous honours and friendships he had won, and presented his large collections of manuscripts, natural history specimens, and drawings to the nation.

We arrived at Gorakhpur, in the United Provinces, on February 6th, and met Colonel Manners-Smith, who had kindly invited us to join him in camp at Bikna Thori, on the Nepal frontier, to see a kheddah which had been arranged to take place near the locality

where King George had such grand tiger-shooting when he was in India for his coronation. We arrived at the frontier by rail, and rode up to a camp in the low outer range of hills which enclose a flat, and in some places marshy valley, a little higher than the Terai. The usual system of catching elephants in Nepal differs from that adopted in other parts of India which I am about to describe, and is much more dangerous both to the pursuers and the pursued. It consists of driving the wild elephants into a valley where they can be surrounded, and then, after separating those which it is intended to catch from the herd, overpowering them by special fighting elephants and tying them up separately. In these fights many of the elephants are injured, and fatal accidents to the men employed are not uncommon. But on this occasion the Nepalese Government had determined to try the system of kheddahs usually adopted in Assam and Southern India by the Indian Government, and had obtained the services of Mr. Armstrong, of the Bengal Police, and of some of the skilled elephant-catchers formerly employed by the Government Kheddah Department at Dacca, which has now been disbanded. This valley and the hills surrounding it are of much the same character as the Dehra Dun, and are covered on the dryer land with forest, mainly composed of sal and other trees, often of much larger dimensions than those in the Dehra Dun or in the Sikkim Terai, and in the open and more marshy parts by a heavy grass jungle, which forms a sanctuary for wild elephants, tigers, rhinoceroses, and other game which are preserved for use and sport. At this season the country is dry, cool and healthy, but in the rainy season very hot and malarious. The next day we rode on to the large camp which had been formed for the men employed in the elephant-catching operations on the banks of a river, and found that a considerable number of wild elephants had already been surrounded in a piece of forest about four miles in circumference, bounded on the south by the outer range of hills, on the west by a river whose bed was now partly dry and open, and partly covered by grass and reeds high enough to conceal elephants. The force employed to effect this surrounding consisted of two regiments of Nepalese soldiers directed by the General-in-Chief of the Nepalese army. After the wild elephants, about thirty in number, had been surrounded, a line of guards was immediately stationed at posts fifteen to twenty yards apart all round the forest. At each of these posts three soldiers were on guard, who built themselves grass huts, and kept fires burning all night to keep the wild elephants from breaking out. Our camp was on the low banks of a river overlooking the scene of operations and close behind the guard-line. The first thing to do was to select a position for and build a stockade into which the elephants could be driven, and in this matter the old Jemadar from Dacca, a veteran of seventy years who had spent his life in this work, was the best adviser. He insisted in going alone on foot into the ring where tigers and rhinoceroses were known to be at large with the wild herd, in order to choose the most suitable place. For long experience has shown that wild elephants cannot be driven like cattle, and it became evident, from the frequent attempts which they made at night to break out in a particular direction, where was the best place to build the stockade. This took three days of hard work, as a large number of strong posts fifteen feet long by eight to ten inches in diameter had to be fixed in the ground and supported by struts and cross-bars strong enough to resist the pressure of the herd when driven in. The stockade was a circular space fifty feet across, with a falling gate on one side, suspended by ropes which were cut to let it drop. From the entrance a narrow lane of strong posts extended for two hundred yards, gradually widening into two wings, which opened out like a funnel, and were extended by a line of cloths hung on poles, to form a lead into the mouth of the alley. The walls of the stockade and the lane leading to it were covered by grass and branches so that the elephants might not suspect danger too soon. During the four nights that we were in camp waiting for the stockade to be built, there were constant alarms at various points on the line, as the wild herd, after drinking in the river—where we could often see their backs and hear their trumpeting and screams from our tents—made efforts to find a weak spot in the guard line. On the second night a wild tusker, supposed to be a rogue, broke into the surrounded area from the outside, and made the enclosed herd very uneasy. This tusker was very bold, and one night, just after dinner, he came down and stood within twenty yards of the fires where a crowd of excited men were yelling and firing blank charges in his face, and we quite expected that he would attack and break out. But though we saw him quite close in the moonlight, he eventually retired and the camp

became quiet again. On February 12th, after several alarms in the course of the night, which must have been a trying and anxious one for the guards, who had now been for four consecutive days on duty, Mr. Armstrong announced that all was ready, and that about eleven o'clock, when the elephants were generally quietest, the drive would take place. Two platforms had been erected above the stockade into which we climbed, and the driving-party, under the command of Armstrong and the old Jemadar, were mustered. The Nepalese were selected from the most experienced jungle-men, and between every two of them one of the Dacca men accustomed to this work was placed. Absolute silence was ordered at the stockade when the party marched off in two lines, which spread out from the stockade and swept the whole of the forest within the guard-line, and when the leaders met on the far side, perhaps a mile away from the stockade, gradually closed in towards it. After waiting an hour or so we heard a great noise accompanied by many shots from the guard-line, which told us that the elephants were on the move, and the noise came nearer and nearer till we thought that the herd must be within the wings of the stockade; but after a time the noise died down, and for an hour nothing more was heard. The same thing happened again, and at last Armstrong came back to the stockade, very hot from his exertions, and told us that the Nepalese drivers were so excited and keen that he could not keep them in order, and that on the first occasion the elephants were on the point of entering the wings but were so frightened by the noise that they broke back. After a consultation it was decided, on the advice of the Jemadar, to remove the cloth screens to another position where the grass was thicker and wait a bit before trying another drive. This was done, and about 5 P.M. a final and successful effort was made. The elephants came on within the screens, and then Armstrong and his men lit grass fires behind them, and by dint of firing and yelling got them on the move towards the alley, into which an old cow first came rushing down. The others followed her, and as soon as they were all within the wider part of the alley the crowd of men yelling and firing rushed them forward in a long line. We could only see their backs as they came down the alley one after another and entered the stockade with a rush. The rope which held up the gate was cut a little too soon, shutting out one or two of the hindmost elephants, but these were determined to follow their companions and forced their way through the gate, which was so hung as to push inwards. The whole herd was then inside, and until it was dark they continued to go round and round in a dense crowd, whilst the men who surrounded the stockade prodded their trunks with spears or fired blank cartridges in their faces when any of the larger ones tried to force their way through. It was very curious to see the way in which the youngest elephants, of which there were three only a few months old, managed to save themselves from being trodden down, by keeping between their mothers' forelegs, and the care which their dams took to protect them. As it was then too late to begin to tie up the animals, we left the stockade at dark to the care of the guards who had now left their posts and come to the stockade. Next morning we returned to see the process of roping and leading out the elephants; but though several of the finest and strongest tuskers were brought into the enclosure the mahouts seemed unused to the work they now had to do in such a dense crowd of elephants. There was not room enough for the noosers to go in on foot, and the constant movement of the crowd surging round and round made it very difficult to get nooses on their feet from the outside. This work requires experience which the Nepalese had not previously had, and from the pictures I will show you, which were taken at a kheddah in Southern India where they have more experience in noosing in a stockade, it seems that they are there more adept in what seems a most dangerous work. But though the mahouts had spears with which to prick the trunks of any wild ones which might attempt to touch them, I never saw one offer to do so. Many of the captured elephants now seemed very tired and thirsty—as well they might be after such days and nights as they had endured—and we never thought that the young ones would have survived; but though it took three days before the whole thirty-three elephants were finally tied up and pulled out of the enclosure, not one was seriously hurt, though several of the oldest were released as not being worth the trouble of training. I will not occupy your time any longer with an account of this process, which has been well described by Sanderson and others. But though native mahouts, who have spent their lives among elephants and have inherited from their fathers a knowledge of their management in health and in sickness which few, if any,

Europeans have ever acquired, I believe that a lover of animals who would pay the same attention to elephants that many Englishmen do to horses would learn a great deal which would be valuable in managing the elephants which are still indispensable in the forests of India, and might be even more useful in some parts of Africa.

Ten days later we arrived at Raxaul, a frontier station a little to the east of Bikna Thori, where the Resident has a bungalow, and where he had made arrangements for our journey to Katmandu. The first stage of thirty miles through the level plain of the Terai we made in doolies carried by bearers, and at daylight we found ourselves in the Sal forest near Churia where the outer range of hills begins. Here we breakfasted and went on horseback over a low rocky sandstone range in which *Pinus longifolia* is a noticeable but not important tree; and passing through a narrow gorge, where in many places the dry river-bed is the only road, sometimes impassable in the rainy season, we crossed an open valley where the cotton trees, *Bombax malabricum*, were of great size. The one of which I show an illustration was 120 feet high by 30 in girth at five feet from the ground, and about 60 feet round the buttresses at ground level.

We then followed the banks of a river along a road practicable for bullock-carts and wooded with tropical trees, but not nearly so luxuriant or so varied in its vegetation as a valley in Sikkim of similar elevation would have been. The large white blooms of a shrubby climber called *Beaumontia* were at this season the only striking flowers I saw, and along the road there were but few birds to be seen, as numbers of bullock-carts were constantly passing. In the evening we reached Bhimphedi, a large village at the foot of a steep range of mountains over which the path is quite impracticable except for coolies; and here we were met by a party of men with doolies and torches, who surpassed all the bearers I have ever seen in their power. For to carry a man of my weight in the dark up a winding path on a gradient of thirty to forty-five degrees and covered with rolling stones was a work I should hardly have thought possible till I experienced it; and they only stopped for a few moments to relieve each other on an ascent of over 2,000 feet. Near the top of this mountain, the Resident has another bungalow at Sisagarhi, between five and six thousand feet above the sea, where we found dinner and beds ready. Next morning we had a fine view over the outer hills, and found rhododendrons in flower and evergreen oaks all around us on the dry grassy hillsides, reminding me far more of Chakrata in the North-West Himalaya than of anything in Sikkim. Next morning we went on with the same doolies, and after crossing the ridge at about 7,000 feet descended on foot by a very steep rocky path through a fairly thick forest on the north side, where, though some orchids appeared on the trees and climbing plants and ferns were numerous, the whole aspect of the vegetation was utterly unlike the much damper forest at similar elevations in Sikkim. At the foot of this mountain we found ponies kindly sent by the Maharaja, and turned north-west up an open dry valley, cultivated in places with wheat and mustard as winter crops in small terraced and irrigated fields, and passed over bare grassy downs on which a plantation of *Pinus excelsa* had been made. The villagers' houses were built of brick and roofed with tiles, mostly two-storied, the upper floor being inhabited by the people, and the lower used for cattle and stores. A small primrose, *Primula Munroei*, a Polygonum like *P. vaccinifolium*, and a small stemless *Tragopogon* were the first signs of spring. Crowds of Hindu pilgrims on their way from the plains of India to a religious festival at Katmandu were on the road, nearly all walking, but a few riding or carried on coolies' backs. Among them were large numbers of women, who caused my companion, new to India, to remark that this was the only country he had ever seen where it was possible to pass thousands of women without a smile on the face of one of them. The contrast between their resigned and melancholy expression and the smiling faces of the Nepalese women, who crowd the bazaar and as porters welcome the stranger on his arrival at Darjeeling, is very striking. In the afternoon we ascended another steep ridge through forest mainly of evergreen oak, and at the top had our first view of the great open valley of Katmandu with the snowy mountains in the background. The great open valley terraced and cultivated wherever possible, with the city of Katmandu in the middle of it, and bare mountains covered with brown grass and scrub on the south exposure, formed a scene which, though beautiful in itself, was so unlike and so very inferior in grandeur to the scenery of Sikkim that I could hardly believe I was only two hundred miles to the west of that enchanting country.

Pilgrims, and coolies carrying immense

burdens of ironware and European goods on the way to the valley, crowded the path; whilst those returning were mostly laden with coarse dirty wool from the interior. The last descent was so steep and difficult that a horse-dealer bringing horses from Kabul had some trouble in getting them down. At the bottom we found a good road and a well-appointed pair-horse carriage waiting to take us to the Residency, where we were hospitably received by Colonel Manners-Smith.

It is difficult, if not impossible, for anyone who does not speak fluently the language of a country he visits, and who has no opportunity of conversing freely with the people in their own language, to form a correct opinion of the economic or social condition of its inhabitants, especially when restricted to a very small area surrounding the capital. But after many years of travel in Asiatic countries, including Asia Minor, Siberia, Japan, Formosa, China, Java, the Malay Peninsula, and with an intimate knowledge of Sikkim and other parts of India dating back to 1870, I formed the opinion that the Government of Nepal is a form of government well suited to the ideas of Oriental peoples. Though the rulers of Nepal have rigidly kept their country free from European education and commerce, and have strictly adhered to the tenets of their own religion and customs, yet the facts that the people appear healthy, happy, and not over-taxed, that the standing army is one of which any Oriental State may be proud, and that law and order prevail to an extent which has kept the relations of their people and ours peaceable and friendly for a very long period, prove that such a form of government has advantages which modern reformers cannot overlook. And when the internal condition of Nepal is compared with what it was in Brian Hodgson's time, when bloody quarrels amongst the ruling chiefs and members of the Royal Family were common, one must admit that for a country where the land suitable for cultivation is insufficient for the maintenance of an increasing population, and where the natural products offer few openings for trade or manufactures, Nepal is in many respects fortunate. I cannot help remarking the difference which exists in the friendly relations between British officers, soldiers and tea-planters, and their Nepalese soldiers, comrades, and labourers, with the attitude and comparative want of sympathy between Europeans and most other natives of India. One cannot work long with Nepalese without acquiring a respect and liking for their pluck, endurance and cheery goodwill under conditions of danger and hardship; or ignore the devotion they show to Englishmen who treat them properly and understand their ways. As pioneers on the North-East frontier of India they have no rivals, and though there is much difference between the various castes and tribes, yet, on the average, I prefer them to any other natives of India with whom I have had to do. The fact that we are able to recruit and maintain no less than twenty battalions of the best native infantry in India entirely drawn from Nepal, and that the labourers employed in the large and important tea industry of British Sikkim have been almost entirely supplied by Nepalese immigration, proves the importance to British India of our friendly relations with Nepal.

The Maharaja has done much to improve the native breeds of cattle, and has imported from India and Europe bulls of various breeds with this object. He is also trying to improve the sheep with rams from my own flock. The native sheep are a large coarse-woolled breed, similar to those kept by the Nepalese on the frontier of Sikkim and commonly brought to Darjeeling for mutton, and are able to endure the cold and wet climate of the higher ranges better than the improved breeds in England would probably do; but below, about 6,000 or 7,000 feet, it is not a country generally suited to sheep, though goats are numerous.

Buffaloes are kept in large numbers in the Terai, and are valued for their milk and meat, but do not seem to be used for agriculture as much as in Formosa, where on steep hillsides, lying with a slope of twenty to forty degrees, narrow irrigated terraces are ploughed by buffaloes, which are much more active and better climbers than their normal habitat would lead one to suppose.

In Nepal, as in Sikkim, most of the cultivation is done by hand labour, and irrigation is general wherever water can be brought. In the dry weather it was impossible to judge of the crops, but the rice and maize stubble did not indicate such good soil as in Sikkim; and I believe that the area of land available for cultivation at healthy elevations is in most parts of the country too small to allow much increase in the population, who emigrate in increasing numbers to Sikkim and the frontier districts of Assam.

Both sexes from their childhood acquire the habit of carrying very heavy loads on their

backs, especially the tribes of the higher levels, who carry on nearly all the trade between Nepal and Tibet in loads of from 80 to 200 lbs. over paths that would be impassable to beasts of burden.

The forests of Nepal do not seem to have received from the Government anything like the attention they deserve, as the growing scarcity of timber in Bengal and the United Provinces must make them valuable in future if they were properly protected. A partial survey has recently been made by a native officer, lent by the Indian Forest Department, but I could not hear that anything had as yet been done to bring them under systematic management. Neither tea nor camphor, both of which would no doubt grow as well as they do in Sikkim, are grown, though I believe that camphor might become a valuable and profitable product.

Whether the necessity for increased revenue to pay for the many kinds of European goods which the Government and upper classes are requiring in larger quantities, will eventually induce the Government to pay more attention to trade and industry than they have done at present is a problem that time alone can solve; but up till now no permission has been given to any foreigners to embark on such enterprise —Nepal for the Nepalese being the fixed policy of the past and present rulers.

Of the natural history of Nepal I can say little from personal observation, because we were not able to visit the mountains of the interior, where are found a great variety of birds and animals which have been described many years ago by Hodgson, who, during his long residence, employed native collectors to procure, and native artists to draw, all that he could get. In this way most of the rarer animals which inhabit the central Himalaya were first made known to science, but of their distribution little is known. There are a number of genera represented in the north-west Himalaya by species different from those which are found in Sikkim and Bhutan, and it would be very interesting to know where these species meet, and whether they overlap and interbreed. But the mountains nearest to the valley, where alone the Resident and his friends are allowed to go, are too low, and so little virgin forest remains, that their fauna and flora are much poorer than those of Kumaon, Garwhal and Sikkim. In the Maharaja's grounds at Katmandu we saw three living deer which had been caught on the frontier of Tibet and of which little is known to Europeans. One I believe to be a female of the species known as *Cervus Wallichii*, of which a fine male, now in the Zoological Gardens, was presented by the Maharaja to King George when in India four years ago. Another is a male of *Cervus affinis*, which inhabits the high forest-country in the north-west of Bhutan, and whose antlers are sometimes brought by natives to Darjeeling, where it is known as the Shou. The third is *Cervus Thoroldi* = *C. albirostris*, discovered by Dr. Thorold in the country north-east of Lhasa and not known to be a native of Nepal.

In the Maharaja's palace, which is a large modern building in European style, I specially admired the very delicate carving which is done by native carvers in a wood known as Dar. *Böhmeria regulosa*, Wall.; this is a very close-grained red wood, easy to work, and found along the lower hills, but not usually attaining a large size. The immense quantity of fine woodcarving, with which the older houses of Katmandu are adorned, shows the talent of the Newars in this branch of art, which, however, seems to be a dying if not a dead industry, as there are now no professional carvers except those employed by the Maharaja, and no shops where such beautiful work can be procured. The same seems to be true of the workers in copper, brass and silver, who now work only to order, and I cannot help thinking that these arts might be encouraged by making an outlet for their work in British India, where there is now a good demand amongst tourists and residents for the fine metalwork brought from Lhasa, much of which is similar in character to that of Nepal.

To most travellers the buildings, temples and ancient monuments of the towns of Katmandu and Bhatgaon are probably the greatest attraction in Nepal, as their architecture is unique. The photographs which I show will give you a better idea of their character than any words of mine.

A Note on the Photographs of Scenes in the Cities of Nepal.

By Aubyn Trevor-Battye, M.A., F.L.S., etc.

A point that will at once be noticed in these pictures is this: that many of the faces of the streets are clearly not those of the inhabitants of the country; the high cheek-bones, the narrow eyes, the short square build, the general "Mongolian" type associated with the idea of the Gurkha are wanting. These are men

from the plains of India on one of their great pilgrimages to Katmandu. There were many thousands of these pilgrims. For the naturalist, accustomed to search for the origins and causes of periodic movements, such human migrations, and on so large a scale, must needs have an interest. We must remember that although at the present day Buddhism and Brahmanism both obtain in Nepal, where the two are indeed inextricably confused, it was not always so. When the Buddha made his first converts in the Himalayas, five hundred years or so before the Christian Era, he found Brahmanism the established religion of Nepal. Therefore, just as birds, under the memory of the species for a once warm home, go northward with the spring into Arctic lands, so these poor Hindus move northward to a home of the infancy of their faith.

I have seen many pilgrimages—pilgrims from the farthest confines of the Roman Church drawn to Lourdes for healing; pilgrims on their way to Mecca; Russians from Siberian wastes come down to the Jordan for the dipping of the shrouds that will enwrap them when they die; Hindus from far Ceylon bathing in the sacred river at Benares—but this pilgrimage in Nepal was certainly in some way the most remarkable. The difficulties of the road will be evident from the photographs. Of those thousands of struggling men and women many were infirm and aged, some so worn by the hardships of the weary way that they would probably not live to see their homes again; a few who had money to spare for this advantage were huddled up in baskets on porters' backs.

The Gurkha, as far as Nepal goes, only dates from the eighteenth century. We are here concerned with the Newar, the original inheritant of the country. The Newar is Tibetan, as the Gurkha is supposed to be Rajput, in origin. His are the arts, the industries, the agriculture. All, then, that we see here in these pictures—architecture, woodcarving, metal work, stone—is Newar in conception and workmanship. And although the pagoda in principle is Chinese, its detail is so entirely different from that which we are accustomed to see in works on China, its decoration is so vigorous, so unconventional, and so true to life, that Nepal may be said to have a distinct art of its own, and that art expressed by great artists.

The Newar is primarily an artist in wood, and his control over that medium is astonishing. The decorative forms of windows, doors or plinths are not confined to shrines or to houses of the well-to-do; it is a principle throughout the land, some of the poorest country cottages having most beautiful workmanship. The picture of a wayside cottage shows the same form of horseshoe-headed window, with its lattice, that we later find elaborated in the wonderful buildings of the town. For although geometrical design forms the basis of this work, it is not "left at that," as in the lattice screens of India and Burma, but, where the money was sufficient, is overlaid by a complicated tracery of foliage, flowers or animal subjects. These are not only in their main lines true to Nature, and therefore quite recognisable (notice the mango over the doorway), but are arranged in a well-defined scheme of composition in the most artistic way. The ability to portray well-known animals is common even to primitive people; the reindeer of the Cave-men are real reindeer, the antelopes of the Bushmen are unmistakably Oryx or Sable, as the case may be. But these people, each in their day, were the *children* of the world, and their drawings, like all drawings done by children, insisted on detail as the child's eye sees it.

The Newar artist had advanced a long step farther; he was no nursery artist—he had "arrived." He knew exactly how to generalise, how to insist on the big features that gave his plant or his animal its recognisable character and individuality, and how to drop all those details that did not tell. And this was equally true whether he worked in wood or in metal; less so, perhaps, in stone. For all that, when form demanded it, he could be as strictly conventional as a Greek. As examples of this, notice the conventional lotus on the well-head and on the capitals of the monumental columns.

Two types of temple are noticeable in these pictures—the Chaitya type and the Pagoda type. The first is the Buddhist form, the other is Nepalese Hindu. These latter are not found, I believe, in India, if we except one that stands out unmistakably among the temples of Benares—the pious gift of a Maharaja of Nepal. It will be noticed that each story of these pagoda temples is supported by long wooden struts. Recourse to such a device to support an overhanging plinth or other structure is elsewhere common enough; a familiar instance is that of the Ponte Vecchio. But the Newar has gone one better than the Tuscan, for he has carved each strut elaborately from end to end.

The shrines would take a paper to themselves. Two, I think, are shown to-night. They are of wood, metal, and stone. In noticing their

extraordinary wealth of decoration, it is necessary to realise that nothing is introduced without a meaning; that each detail, decorative as is its effect, has a distinct and definite significance in the religious sequence of a people's worship.

The doorway of the Durbar Hall in Bhatgaon is, of course, well known as one of the greatest achievements in metal in the world. It is of copper overlaid with gold. It is, indeed, a thing of fascination; the folds of its serpent seem to writhe, the lizard on its lintel might be darting in the heat.

But of all the remarkable and beautiful features of the streets of these Nepalese cities, nothing holds the attention so strongly as the monumental statues. I do not know whether these are absolutely peculiar to Nepal, or whether they are also met with in Tibet; the writer, at least, had never seen anything like them. They are sculptured portraits of various rulers who built the temple in front of which they stand. First there is a simple base, then a square stone pillar, perhaps 30 to 50 feet high, then a beautiful capital of lotus pattern. On this is placed sometimes a throne of copper gilt, based on animals—elephants or others. On the throne the Newar king is seated, with the cobra or a gilt umbrella as a canopy above him. In some examples his family are about him; in others he sits upon no throne, but kneels in an attitude of adoration before the temple of his gods. No description could adequately convey an idea of the extreme and beautiful dignity of these monuments. What they owe to their surroundings it is impossible to say; they belong to Nepal and not to Trafalgar Square. There are, at any rate on the Maidan of Katmandu, some very fair equestrian figures of Maharajas that are of Western making; and to come upon these after the others was to change the sublime for the commonplace. Seen where they were, these columns of the rulers seemed structurally, decoratively, spiritually, and in their beautiful repose, a final word in art.

DISCUSSION.

Sir Louis William Dane, G.C.I.E., C.S.I., in opening the discussion, said he had been delighted to hear the very high opinion the author had formed of the Prime Minister of Nepal, His Excellency the Maharaja Sir Chandra Shamsher Jung. He thoroughly endorsed all that had been said as to the extreme desirability of maintaining the present cordial relations between Nepal and India. An inspection of the map showed that Nepal lay right on the flank of the main chain of communications between Calcutta and the North-West frontier, and if by any chance the State of Nepal at any future time did not show its present friendly attitude towards India things would be very awkward indeed It was quite true that, on the whole, this country had been friendly with Nepal since the beginning of the past century, but the present very friendly relations were largely due to Lord Curzon, and to the very distinguished statesman who was now the *de facto* ruler of Nepal. Things at one time had drifted into rather an awkward situation owing to the extraordinary dread the Nepalese had of China. In the last century China succeeded in invading Nepal, and the Nepalese were very much alarmed at the idea of a future invasion by China. They were disposed to think at one time that China was quite as big and powerful a country as Great Britain or India; but he was glad to notice after Sir Chandra Shamsher Jung saw Lord Curzon in 1903, when he (the speaker) had the pleasure of making his acquaintance, his ideas on this subject were entirely changed, if he ever had such ideas; and from that time to the present he had most loyally and strongly supported India, and had been a most faithful and true ally of the British Government.

Sir H Evan M. James, K.C.I.E , C.S.I., said that, having had the advantage of visiting Nepal, he quite admitted the beauty of the woodcarvings in that country which had been described by the author, but he thought it was a mistake to praise them at the expense of the other woodcarvings of India. He did not agree that the woodcarvings of Nepal or its art generally were superior, or indeed equal, to those of Ahmadabad, or other places in Gujarat, or even the Deccan. A good deal of Chinese influence was noticeable in the pagoda-like temples, but a great many of the remaining features were to be found in other parts of India. For instance, in the south of Orissa there were several beautiful pillars to be found, which might almost have been a copy of the tall pillar shown in one of the photographs, with the great Garuda, the famous bird of Vishnu, on the top of it. It was not at all uncommon when a traveller saw a rather unknown country to admire it extremely, but personally he did not think that either the house or the temple architecture of Nepal was better than in the provinces which he had named. He was anxious to speak up for old friends as well as for new.

Mr. R. A. Leslie Moore said he simply desired to ask two questions. The author had stated that the Gurkhas were descended from Rajputs. He did not contradict that statement for a moment, but he would like to know how it was that they were so different in stature and in appearance from the Rajputs. The Gurkhas had Mongolian features and the Rajputs had not. His second question had reference to the statement made by the author that when he went through the city of Katmandu

he was accompanied by two or three guides, or rather guards. Was it the case that Europeans were so objectionable in the city of Katmandu that they could not go about without guards?

Mr. Elwes, in reply, said that the criticisms that had been made by Sir Evan James were directed to the statements that had been made by Mr. Trevor-Battye, and not those made by himself. Personally, he thought that Mr. Trevor-Battye, not knowing the woodcarving and architecture of other parts of India as well as Sir Evan James, had slightly exaggerated the peculiarity and beauty of the Nepal woodcarving and architecture. He knew that was the case because he had seen similar things in Kashmir and other places; but, taken as a whole, everyone must admit that Katmandu was unique. The statements to which Mr. Moore had referred were also made by Mr. Trevor-Battye and not by himself, and he entirely declined to take responsibility for them. Whatever was the origin of the Gurkhas, he thought their stature and their character also had been enormously changed by their mountain habitat. He agreed that the Gurkhas had Mongolian features, and had definitely stated that some of the tribes with whom he was acquainted were very Mongolian indeed. He was not sure that many of the Buddhist tribes were not in most cases pure emigrants from Tibet. The best camp cook he ever had was a Jurga—a Nepalese. He was a pure Buddhist, and said his prayers like a Llama every morning before he brought him his breakfast. The mixture of the tribes was very considerable. He thought Mr. Moore had rather misunderstood what he meant to say with regard to his guides or guards in Katmandu. He and his friends were visitors of the Resident; they had two or three Nepalese chuprassees, and a whole crowd of people following them about, and under those circumstances they did not have the same facilities for observation, for sketching or photographing, as they would have done in a place where they could walk about as they pleased.

Mr. G. W. Christison said he intervened with reluctance even for a few seconds at this prolonged stage of the proceedings. Having had long experience of the Nepalese military castes in working Darjeeling gardens, it would be disloyal not to express entire agreement with all that Mr. Elwes had said in praise of the Gurkha. With tactful, judicious, sympathetic treatment they were adaptable and became very competent, though the planters, owing to methods too common, unfortunately, had not always made the most of them, in their own interest or that of the proprietors. He was glad to bear testimony to the more intelligent men amongst them having for twenty-five and thirty-five years given service as conscientious as mortal man could render. On this account he would remember such men as friends as long as he lived. He rose to allude to deforestation, a matter of vital importance, especially in such a mountainous country, where the damage done was often at a great distance from its cause. The subject was a wide one, and he made no attempt to deal with it. Darjeeling, the adjacent hill district referred to, had been seriously injured by deforestation within its own borders, and it, as well as the country below, had also suffered from the shameful destruction of forest throughout Sikkim some years ago, for which, unfortunately, the Government of India was mainly responsible. On the Bhutan Hills, on the east, deforestation was also reported to have caused damage in the district below. He had only had a distant look at small portions of Nepal from points on its eastern boundary, from time to time, during the last fifty-one years. In reference to the south-eastern corner of those hills above the Terai, the slopes were denuded of all forest and even brushwood, and of late years were badly scarred by landslips. Though this was the characteristic of Nepal generally, owing to situation, it was not so harmful to Darjeeling district as Sikkim, but it must do some damage to the plains below. For years he did his utmost to induce the Government to take measures to remedy the evil. Five inspections and reports were called for from Forest Department officers, three of which, by Mr. Grieve, were able and illuminating. An Act was also drafted but never passed, and he believed no remedial steps had yet been taken. Planting was costly, requiring care afterwards. The only practical remedy was inexpensive, because providential. It was wonderful how landslips and most of the dangerous zones, if simply left alone, became clothed with protective scrub, and even trees of a kind, unaided by man. All that was required was inexpensive fencing to prevent trespass of cattle and goats. The loss of profitably productive soil was rarely necessary to give security. He wished Mr. Elwes—than whom no one living was competent to give more valuable testimony—would kindly inform the meeting on two points: did he consider deforestation existed to the same serious extent throughout Nepal as in Sikkim and Darjeeling; and how did the present condition of deforestation throughout Darjeeling hill district and Sikkim compare with what he observed during his first visit to those parts many years ago?

Mr. Elwes, in reply, said that to go into the question of the afforestation of Nepal or Sikkim would take much more time than he had at his disposal, and he was not prepared to do so at the moment. He could, however, absolutely confirm what Mr. Christison had said as to the vast, ruinous, and, he would go as far as to say, disgraceful destruction of invaluable virgin forest that had taken place both in Sikkim and in Nepal since he first knew the country. It so happened that the Nepalese forests through which he passed were very much better preserved, partly for the purposes of game, than the Indian forests, and there had been no devastation of the outer hills in Nepal, such as

there had been in some parts of Sikkim. But in the interior, where the land lay at a higher altitude, he believed the devastation in Nepal had been even worse than it had been in Sikkim. Those, however, were matters on which there would always be differences of opinion, and it was much too large a subject to deal with that afternoon.

Sir Steyning William Edgerley, K.C.V.O., C.I.E. (Chairman of the Indian Section Committee), in proposing a hearty vote of thanks to the author for his instructive and interesting paper, said that in December, 1914, this country had hoped fittingly to celebrate the existence for a century of "a scrap of paper" embodying a treaty which was made between America and England. In March of next year they might equally celebrate with Nepal the existence for a century of another "scrap of paper," the Treaty of Segauli, which had remained in force from March, 1816, up to the present time, and which he trusted would still remain for many years to come. It was possibly a great advantage to the Nepalese that the treaty was not made with the Germans.

Mr. Elwes inquired whether it was not unique in history that a treaty between an Oriental and a European country should remain absolutely unbroken for a century. Was it not at the same time highly creditable to the rule of Nepal that such a thing had happened?

Sir Steyning Edgerley replied that Sir Louis Dane was more competent than he was to deal with that question, but, speaking on the spur of the moment, he thought he could remember at least two other treaties settling our relations with Indian States which had existed practically as long as the Treaty of Segauli.

Sir Mancherjee M. Bhownaggree, K.C.I.E., in seconding the motion, said the paper had been of surpassing interest, as it dealt with a country about which so little was known. At the present time everybody was curious to learn more about it, as it was the home of that brave soldier the Gurkha, who was now taking his share, as a subject of the King-Emperor, side by side with his British comrades in defending the public law. One of the points he noted with great satisfaction was the tribute the author paid to the characteristics of the people of Nepal. Mr. Elwes had stated that there was a sort, if not of kinship, at least of affinity between the natives of Nepal and British people. That showed that the author had approached the subject in a very sympathetic spirit, and for that as well as for his very interesting and instructive paper he was entitled to their very best thanks.

The resolution of thanks having been put and carried unanimously, the meeting terminated.

Mr. Trevor-Battye communicates the following note in reference to the remarks on his paper made in the course of the discussion:—I am sorry if I seemed to claim more knowledge of Nepalese art than I really possess; this is little enough. Nor have I travelled in the Deccan, nor seen the cities south of Orissa. I did pay considerable attention to architecture—structural and decorative—in Gujarat, and particularly to that in the city of Ahmadabad. Whether the extremely interesting work of this city is more or less beautiful than that to be seen in the cities of Nepal is after all a question of personal feeling; I find it difficult to compare the two, for, as I am sure Sir Evan James would agree, they are more remarkable in their differences than in their resemblances. I am afraid I cannot help with Mr. Moore's question. If the Gurkhas were from Rajputana, as they are said to claim, it certainly would seem strange that they have so greatly lost that type. [We had Gurkhas at the kheddah who were not at all Mongolian in feature.] But if under the Mohammedan advance they severed to a great extent their connection with India, favouring rather relationship with Tibet, intermarriage might bring about the change? Probably the population of Nepal is now of a very mixed character, and the Mongolian type seems to be more or less common to all the mountain folk.

NINTH ORDINARY MEETING.

Wednesday, February 10th, 1915; Carmichael Thomas, Chairman of the *Graphic* and *Daily Graphic*, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Dubash, Peshoton S. G., 135, Highbury New Park, N.; and care of Pestonji Bhicaji, Kimari, Karachi, India.

Lowton-Brain, L., Director of Agriculture, Kwala Lumpur, Selangor, Federated Malay States.

Mason, Charles Thomas, Sumter Electrical Company, Sumter, South Carolina, U.S.A.

Murfee, Professor Edward Hunter, A.M., LL.D., Brenau College, Gainesville, Georgia, U.S.A.

Vaishya, Ramjidas, Sweet Cottage, Gwalior, Central India.

Van Deventer, Harry R., Sumter Electrical Company, Sumter, South Carolina, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Dean, Oliver H., A.B., LL.B., 116, East 36th-street, Kansas City, Missouri, U.S.A.

Parris, Hamilton Harcourt, The Croft, Grenville, Grenada, British West Indies.

Taylor, H. Blake, 22, Cromwell-crescent, S.W.

THE CHAIRMAN, in opening the meeting, announced that the author was, unfortunately, ill and unable to attend the meeting, and the paper would, in his absence, be read by the Secretary of the Society, Sir Henry Trueman Wood.

The paper read was—

BRITISH LITHOGRAPHY IN 1915.

By F. VINCENT BROOKS,
Member of the Senefelder Club.

We live in a time when many things are in the melting-pot, when many changes are advocated by many different authorities.

Most of us are divided into two classes—those who, even if, like myself, they are no longer young, yet have an ear attuned to the least whisper that breathes the language of the arts and crafts that they love, and those who stand four-square opposed to every form of innovation. Lithography, like its sister arts, has its advocates of new developments, its defenders of old methods, and to one or other class must of necessity belong our chief modern workers—Mr. Joseph Pennell, Mr. Frank Brangwyn and Mr. Spencer Pryse, Mr. Ernest Jackson, teacher as well as artist, and therefore more capable of understanding the difficulties of our craft, and many others, my colleagues of the Senefelder Club.

This may not be a favourable opportunity to speak of the personal side of the question, for we have been sorely tried recently; but still do I hope that at the close of this appalling war we shall still be a strong England and able to indulge in some of those ideals that have stood us in good stead in the past: to take a notable instance, the welcome given to the French refugees who came to us after the Massacre of St. Bartholomew's Eve. These splendid people brought their art and crafts with them, settled among us, and became of us; and there are probably few in this room whose blood has not been enriched by the infusion.

I am wanting you, my friends in the trade, to adopt this principle in regard to those whom I am inclined to describe as the neo-lithographers. I invite you to let their influence have free course among you, so that we may build up a school of British lithography which, in the fierce competition of the nations, shall be without fear and without reproach.

When I last took up my pen to write on the subject of lithography the year 1910 was drawing to a close, and my purpose was to write the article on lithography in the then forthcoming edition of the "Encyclopædia Britannica." One is now surprised to find how much has happened in the short space of time that has intervened; but probably nothing has happened of equal importance to that which has occurred in regard to it since the beginning of last August, and I should seriously belittle my opportunity if I did not give a front place to this branch of my subject.

The United Kingdom of Great Britain and Ireland is probably the largest user of lithography in the world, and if the total of our national production and our imports were divided by the number of our population, we should be surprised at the sum per head that would be the outcome of the operation; but so great is the foreign competition that it is estimated by competent authority that 40 per cent. of this sum comes from abroad.

Now it is abundantly clear that the war will throw upon every trade burdens that will be felt for many years, and the paramount question for each trade is to ascertain what vantage can be secured from existing conditions that will enable it to meet the necessary charges that are being piled up against it. There is no remark so frequently heard as this: "Surely what can be done in Germany can be done here!" Can it? Let us turn the question about—it is always a safe process—and ask, What success has Germany when she endeavours to rival us in the finer counts of cotton piece goods, for which the humid atmosphere of Lancashire is so conspicuously suitable? What success has she when she endeavours to rival the product of Etruria and Worcester? Her efforts will find better recompense if employed in keeping up the quality of her own Dresden china. Can Germany rival Paris fashions or grow a Ribston pippin? It is a main point of my contention that nothing is to be gained by a slavish imitation of German methods, and that our aims will be better served by using our period of freedom from pressure by perfecting British work in every possible way, by educating our people to delight in the work for which our English artists and lithographers are so well suited, and at the same time learn all we can of that efficiency of administration that has stood the German lithographers in such good stead.

To descend from the general to the particular. Let me deal with the question of Christmas cards, of which we have heard so much of late. By far the largest user of such articles has been Great Britain, so that the British people have called the tune; what they have asked for has been a matter of evolution proceeding from the

valentines the modern cards superseded. These were of two types—such as when a tiny Baxter print of great finish was displayed on a vast piece of embossed paper, or when a quasi-comic idea was developed in a crude outline and vulgar colouring; and, needless to say, the more elegant idea went ahead the more rapidly.

If German printers had been left to themselves they would have kept on these lines, for the cult of high finish and the infinitely minute is their strongest point, and on these lines—in which everything is more or less a miniature—the English printer has little chance of attacking them successfully. For, in the first place, a tremendous quantity of carefully trained art labour is requisite, a quantity that is non-existent in this country, and a precision of register in vast sheets, generally 50 ins. by 40 ins., and that is almost hopeless in this country, owing to our more varying temperature, and more especially on account of varying conditions with regard to the humidity of the atmosphere.

It is possible to deal with the question of temperature, but it is a difficult thing to deal with the question of moist or dry atmosphere—that is practically to say of an easterly or westerly wind. Mr. Horace Hart, the well-known printer to the Oxford University, has, backed by large funds, brought about a condition in this respect by which he is able to do a very high grade of collotype in colour, but that is a very different thing from having the natural atmospheric condition as it exists in the great central plateau of Europe, on which the chief printing centres of Germany are located.

The absence of this quality in the air causes the English printer, for work of such close register, to prefer a sheet, say, 35 ins. by 25 ins., whereas a sheet of 50 ins. by 40 ins. is a frequent measurement abroad, and thus a sheet of more than double the area is printed with the same revolution of the machine.

The second point of vantage that the foreigner possesses is the much less cost, and, I must confess, the much better character of his transferring, by which is meant the putting on the large stone or plate the necessary repetitions of the originals that have been drawn on quite small sheets, and this transferring is a very important item in the total cost. The total volume of this work done in a German factory is very large, so that it is much cheapened by subdivision; a workman is constantly employed pulling the barest possible transfers, so bare that the solids generally have to be filled in on the stone or plate; this work is carried out by quite an army of girls, other girls having previously stuck up the transfers on the backing that is the size of the full sheet to be printed. This is work for which women are exceptionally well suited, but such employment would be contrary to general usage in this country, and, I imagine, would meet with sturdy opposition from the trade unions; but unless working arrangements of this sort can be made, the British printer will be hopelessly out of it, both with regard to cost and general efficiency.

When the sheet is what is called "stuck up" it is passed on to still another printer, who, in a large factory, spends all his time in pulling such sheets through upon the stone, always in a broadway press, which is a great essential, though at present little seen in our workshops. The plate then goes to yet another printer, who rolls it up and leaves it ready for the machine, and the result of all this subdivision of labour is that at a cost of 10*s.* a process has been gone through that would cost 30*s.* in most English establishments.

The strong point of English lithography is in working from original stones, as is done in our vast poster industry, and in nearly all such cases the work is done in mixed chalk and ink, instead of ink only, and this is much less expensive. This work, when printed by the offset process, secures an amount of finish that makes it a very effective substitute for the stippled work of the Continental artist.

When I was last in Leipzig I had full opportunity of seeing the large chromo-printing businesses in operation. In one of these I was glad to find the ubiquitous Scotchman in charge, and on leaving the artist's room I remarked on the large number of young men he had under him. "Do they receive much money?" I inquired. "No, no; they are nearly all volunteers." "What do they do when they have learned their trade?" "They go for their 'wander-year,' and then generally find work in America, and thus avoid military service"—and I felt thankful that the demon of commercialism had not yet led us into such devious ways of bringing up our youngsters in blind-alley occupations.

Mention has already been made of the vast nature and satisfactory condition of the poster industry in the United Kingdom; its progress in efficiency and quantity during the last two decades has been remarkable. The United States were in 1888 immensely in advance of

us, and this had largely arisen from the fact that the Storbridge Lithographic Company had the acumen to put that distinguished English artist, Mr. Matt Morgan, in absolute control. Morgan, apart from his work in the *Tomahawk*, was a wonderful scenic artist, and carried out two stupendously beautiful sets of scenes for pantomimes at Covent Garden, under the management of Charles Harris the elder. This theatrical gift led him, unfortunately for his art, into a groove, and all his work was of the stage — stagey. His figures and animals always seemed to be posing, as in the case of the huge posters done about this time for Barnum's first visit to this country with his show. Much has happened since then. England has gone straight ahead, and a recent collection of American work shown at the Printers' Exhibition in the spring of last year was beneath contempt. Can I account for this rapid progress? I think I can, and I attribute it to two causes—the artists have taken an intense interest in the matter, and the buyers of such advertising matter have almost invariably insisted on the name of the artist being on the picture when reproduced. Apply the same principle to the Christmas card artist, allow him to see it through the press, and one half of the much-talked-of Christmas card question will vanish into thin air.

A further immense advance will be made in this field on the day that the printer's name becomes visible on every card that has any pretence to be even a tiny work of art. The publishing houses are vast organisations, and they are jealous of giving to trade rivals information that may be useful to them, but what is to prevent them making their contracts with their artists and printers for having their exclusive output? It is a regrettable incident that something of this sort is creeping back into the poster and show card trade, and users, on the ground of perhaps saving trouble, are dealing with large organisations that employ a well-dressed traveller who knows all the tricks of his trade only too well, a well-known designer or two, and then exploit the printer to the obvious detriment of reproductive art.

There is a piece of beef figuring on the walls at the present time that has often sent me to my lunch prematurely; lithographically it is the work of a much-respected competitor of mine. The work of the artist must have been good, though, after all, it is only a piece of very "still life," but it took a master of his craft to execute it in lithography, and it appears a cruel irony that no mention of the firm's name appears on the poster.

As long ago as 1884 a very capable man, who had been brought up in Messrs. Marcus Ward's at Belfast, became manager of a firm of German origin, and he decided that for once he would let himself go and have a set of cards to his own liking and regardless of expense. He commissioned my friend Wilfrid Ball to make him thirty-six suitable sketches, and gave me a good price to lithograph them under the direct control of the artist. The result was a pronounced success, and the cards sold out immediately. But the real object of the manager remained to be seen, for he had a full sheet of the cards pinned behind his editorial chair, and I have had many a good laugh when he has called for a German printer to be admitted, despite my presence, and has said to him, "You recollect those landscapes that I gave you the other day; I want to show you what English landscapes really are," and he conducted him from Epping Forest to Burnham Beeches and Windsor Great Park, bright sunny bits every one, and finished up by saying, "Now don't give me any of your Black Forest stuff, for I won't have it!"

Although, for reasons of price, I received few further orders, I had ground for knowing that some German renderings of English landscapes were less horribly gloomy stodgy things than they would otherwise have been.

A couple of days before the breakdown in health that has deprived me of the pleasure of reading my own paper, the idea occurred to me that it might be a desirable effort to place before those present an example or two of the direction in which our thoughts might turn in view of the present situation. I had therefore given instructions that a subject by Mr. Wilfrid Ball and another by Signor Barberro should be lithographed on the lines that I have already suggested, with a view to presentation to the members of the audience. I especially stipulated that the drawings should be copied with some freedom, and that there should be no high finish attempted, my desire being to cut right adrift from the tightness which has been the *bête noire* of such work. It has never for a moment been my wish to suggest that a great number of my competitors could not do the work equally well, but I felt it desirable to supply my meal on the assumption that some of them would supply their malt, and that between us we might, by this co-operation, mark the advance

which I feel to be so near at hand and easily available.

These cards are printed by the flat-bed offset process of lithography, by which a sheet of rubber takes the impression from the stone, and then by a subsequent cylindrical pressure is made to yield up its colour to the sheet of paper, the object of this being to enable a satisfactory result to be secured on Whatman or other naturally grained paper. The method of lithography employed is that of chalk and ink mixed, a class of work that has always been typically British. The reason that it has not been applied to Christmas card work is that it is held to deteriorate in transferring to the necessary large sheet. My experience is that this is only a partial truth, and that if the chalk work is of the right sort it is quite possible to get beautiful transfers which, when printed by the offset process before described, will run the German work in this department exceedingly close, and secure a result essentially British at a moderate rate of cost.

The co-operation of artist and printer is the essential point, and if the former has neither the time, the gifts, nor the inclination, to put his work on the stone, and this is seldom possible when there are many colours, he should at least have an important voice in selecting the method of reproduction.

No two artists have got so much out of three or four colour work as Arthur Rackham and Edward Dulac; they have taken note of what the process can do, and each would seem to have concluded that it succeeded best when a result closely allied to "faïence" was aimed at. And I advise those who may draw for the lithographer to engage in their work on lines suitable to the method to be employed.

It is notable in regard to the lithography of the past, that, apart from those instances where artists have worked direct on to the stone or grained paper, those prints are most valued where an artist's work has been used as a suggestion only by a lithographic artist of repute, and the finished work has been an unmistakable print. The crowning vice of the chromo-lithograph of mid-Victorian days was that each print masqueraded as an original; and the accidents of the brush were, to put it in the manner of Dr. Marigold, reproduced as "large as life and twice as beautiful."

My constant advice to the younger men that I meet is that a drawing must be treated as an inspiration; treated with respect by all means, but kept as an inspiration only. It was in that way that the great engravers of the past worked, and it is for that reason that the prints from their plates are so highly valued at this time. A return to this state of affairs in lithography will be the best way to show that the House of the Interpreter, in which so many of us lead laborious lives, has not been built in vain, and that is the spirit in which these two little specimens have been produced.

What is passing through the minds of men is, whether we can not only secure German work during the period of the war, but hold it when the war is over; this depends on the way we use our present opportunity. It is not difficult to foresee that at its close the country will be flooded, as far as legislation allows, with the production of the German printers, and that they will be especially keen for work, and if we have only met the opportunity by laying down additional plant there may easily be over production and a period of depression. There will obviously be a period during which a great preference will be given to home-produced work, but the desire for good value will assert itself with constantly increasing power, and will eventually be our undoing unless we have used our chance in other ways than this.

The needs of the moment are more thought, and perhaps less work, on the part of those who lead; a closer co-operation between artist and reproducer; increased technical education that we may have a higher class of art workers; the abolition of blind-alley occupations; and, mind you, there is such work that has nothing to do with the young people—there is the mechanic's blind alley that ends in the *impasse* of £2 a week, or the curate's blind alley of £150 a year. There must be more rising from the ranks all round, and those who rise should ever be reminded by those in the higher command that he who would direct human beings must himself be humane.

There will arise much improvement in British work when less of it is anonymous; it is this anonymity that has stayed the progress of Christmas card work, and I look forward to the time when the suburban lady will inquire of the shopkeeper, not whether he has the booklet or card of this publisher or that, but, "Have you anything dainty by Arthur Rackham, Hugh Thomson, or Willy Pogany"? "Have you any screamers by Hassal, Cecil Aldin, or Louis Wain"? I have mentioned one case where the personality of the artist worked like magic,

but there have been far too few of such instances; but it is a pleasure to recall series by Kate Greenaway, Randolph Caldecott, Phil May and Frank Paton, which have, by their success, done something to confirm my contention. Nothing can be more clear than that if artists secured all the recompense of their work, and not the cash value only, there would be a great accession to the ranks of those who help in producing these unconsidered trifles, and that there would then arise more freedom, less working to type, and factory-made art would cease to exist.

DISCUSSION.

THE CHAIRMAN (Mr. Carmichael Thomas), in opening the discussion, said that no one was more qualified than the author to speak on the subject, because he and his firm had, for the last fifty years or more, been constantly engaged in reproducing pictures and drawings by means of lithography, and some of the most beautiful prints in existence had been the result of their labours. Some of the old lithographs were very charming reproductions. Many present would remember the reproductions of the Birkett Fosters and Hunts, which were practically facsimiles of the originals, and were far more attractive and artistic for the decoration of the house than the second-rate water-colours which many people put on their walls because they were originals. The soft colours and touches of water-colours, pastels and miniatures were very well reproduced by the good lithographic artists of the day; but, in his view, the strength and vigour of the Old Masters, such as Velasquez and Rembrandt, were better reproduced by the four-colour process of the present day, although Mr. Pennell would probably not agree at all on that point. He was glad the author had referred to the German question, because it was very disappointing for anyone who was interested in printing and prints to know that so much of the work was done in other countries. Mr. Joseph Goodman, in a most interesting paper which he wrote for *Penrose's Annual*, stated that in Nuremberg there existed a factory, employing 1,700 people, constantly producing lithographic work, the whole of which came to England. What a splendid opportunity there was at present for the English lithographers and artists to capture some of that trade! He did not know that the very descriptive saying "cheap and nasty" applied to anything with more truth than in the case of German lithographs. Some time ago, when walking through Kent with an artist who had painted many popular pictures, they entered an inn for refreshment and found hanging on the walls a horrible reproduction of that very artist's work, which was quite unauthorised and a perfect disgrace to him. Personally a reproduction of a drawing gave him more pleasure than the reproduction of a picture. He was thinking particularly of some of the delightful old lithographs that were printed in two printings, one a black reproducing the pencil work, and the second a buff tint with the whites cut out. It gave a charming effect, and he was glad to see that a certain amount of work was done in that way at the present time, both in landscapes and portraits.

MR. JOHN COPLEY thought that lithography had one use for artists, and quite another for a much larger public than artists generally dealt with, and that there was a great danger of confounding those two uses. While lithography could provide for both, the two fields were absolutely distinct. The author had covered one of them; the members of the Senefelder Club covered the other, and if lithography was to progress both commercially and artistically it was essential that the two fields should be kept rigorously apart. It was necessary to realise that one way of drawing on stone, which was the way that lent itself to artistic work, was not capable of infinite multiplication or rapid printing; therefore it did not come within the author's scope. The beauties that an artist wished to retain were beauties that were lost when they were rapidly produced. On the other hand, lithography had an enormous function in providing beautiful things that could be reproduced in large numbers and quickly, and the author desired that function to be made better and more artistic now that Germany was out of the way, and artists could co-operate in bringing that about; but the two must not be confounded, as there was a danger they would be at present. Colour work was perhaps the great field in which lithography of the commercial sort could progress. Artists had tried hard to make colour lithographs, but so far had failed; but for colour work on a large scale it was probably the best medium that existed, and he hoped those concerned in it would go ahead and produce better results than the Germans had achieved.

MR. G. W. JONES, after expressing his regret at the enforced absence of the author, who was a true craftsman, passionately fond of his calling, and who sought that everything that went from his workshop should be worthy of himself, said he wished Mr. Vincent Brooks had referred to the chromo-lithography of the past. Twenty-four or twenty-five years ago some wonderful work of that nature was produced by an eminent Edinburgh firm, but it had been a source of regret to him to find that since that time they had been obliged, through the introduction of the new methods of colour-printing, to depend largely upon them. He had always been a passionate admirer of chromo-lithography, and the excellence of some of the work was due to the fact that the painter did not feel it beneath him to go into the workshop and finish off the various stones before printing was commenced, and even sometimes supervised the printing. It was the spirit of harmonious working between

the artist and the reproducer that made for the beautiful pictures which had been, and still were, the glory of the chromo-lithographer. He hoped they would be able to get back to that high standard, because only by that means would they be able to maintain their position against the Germans.

Mr. Frank Colebrook thought the statement the Chairman had made in reference to the article written by Mr. Goodman was not quite accurate. He believed the correct version was that on the occasion of the visit of Dr. Reynolds, the head of the Manchester Technical Schools, to the works in Nuremberg the whole of the work then being done was for the British market. That was not inconsistent with the possibility that it was habitually so, but he thought it was hardly likely that that would be the regular condition of affairs.

Mr. Joseph Pennell thought the Chairman had made a mistake at the beginning of his remarks when he said that lithography was a method of reproduction. That was just what it was not, and never had been. Lithography was a method by means of which an artist could express himself in his own way from beginning to end; and the trouble with British lithography had been all the way through that the reproductive person had somehow crawled in and thought he was IT. That was the reason British lithography was so contemptible. The author had stated that there was nothing more contemptible at the last Printers' Exhibition than the American work, but personally he did not think there was anything so bad as the British posters, British post-cards, and everything else that was produced by British lithography; it was absolutely beneath contempt. Lithography was an original art for artists and not for other people. That other work could be done in reproductive lithography everyone admitted; it had been done in a wonderful fashion, but when a third man intervened the result was awful. There was exhibited on the wall of the theatre a lithograph done by a most distinguished Belgian artist, who made the drawing after three weeks' study at the London County Council School, which proved how little special genius or instruction was required. It absolutely proved that lithography was an art for artists and for nobody else. The important point was to carry on the tradition or the method which Senefelder invented. The artist alone produced all the wonderful work that had been done in past years. Mr. Copley had referred to the two kinds of lithography, commercial work, which could be beautifully done, and which was worthy of all recognition, and the artistic side of lithography. Lithography was even a more original or autographic method than etching or wood-cutting, because in lithography every line that the artist made, either on the paper or stone, he saw, and when those tones were printed they represented entirely an artist's work, there being no intermediary. The lithograph was not a reproduction, as the Chairman said, but a multiplication of the artist's own design, and the trouble was that the middleman, who was a most ingenious and wonderful person, had come in and copied his designs. He was afraid there would be a fearful row if anybody "translated" his work, as the author called it—in fact there had been rows in connection with his work for the *Graphic*, to which he had had the honour to contribute, owing to the photo-engraver and the printer coming in. In lithography the artist should do the whole of the work himself, and that was the reason the Senefelder Club was promoted and had prospered. A good many secrets had existed in connection with lithography, but when they were solved they were found mostly to be composed of stale beer and lemon juice, which were two of the most vital factors in making lithographs. Senefelder said at the end of his book that the lithographic method was a most wonderful thing, to which he hoped many great and brilliant artists would turn their attention; they would do great work, and the day would be blessed on which he invented it; and he (Mr. Pennell) quite agreed with the statement.

The Secretary (Sir Henry Trueman Wood) said the audience would agree with Mr. Pennell's remark that lithography was an original art, but it was also a commercial business, and the paper was written from that standpoint. Lithography was of importance as a means of reproducing artists' work as well as a means of enabling them to give their own ideas to the world.

Mr. E. J. Sullivan said that the artist had always had some sort of quarrel with the reproducer. In the time of the Chairman's father a great effort was made to bring the wood engraver into touch with the artist; but when speed in multiplication was a necessity it was impossible for the artist himself to carry out his work for the purpose of reproduction. Very shortly after Senefelder's time, Daumier, in Paris, drew a cartoon per day on stone, and these were printed on one side of the paper, type occupying the other side. He mentioned that as an example of the forcible means lithography possessed for giving an artist a chance of absolute autographic self-expression without any intermediary at all except the printer. Twenty-five years ago, when the *Daily Graphic* was first started, and when wood illustration was not a lost art, he remembered that at one end of the studio there was a long bookcase in which wood-blocks were kept for fear the process might break down. A means existed as far back as 1820 by which an artist could express himself in print without a wood-block or any intermediary at all, and he did not know why that lithography went out unless commercialism killed it as a means of artistic expression. Although the Dalziels, the Thomases, the Swaines,

and others presented the artist's work in a magnificent form there was a mind in between the artist and the multiplication of his work. No words could express the exquisite delicate, silvery beauty of the drawings on wood in pencil by Boyd Houghton exhibited at South Kensington, but delicacy disappeared in a reproduction from a wood-block, and a sense of force was apparent which was almost brutal in its insistence. In lithography all those minor subtleties and delicacies were obtained that wood and copper could not possibly give; the stone was capable of giving gradations in length and width of line such as were obtained with a pen, and there was no mind between the artist and the product.

The Chairman, in proposing a hearty vote of thanks to the author for his interesting paper, said he was sure it was also the wish of the audience that the Secretary should convey to him their regret at his absence, and their best wishes for his speedy recovery. In reference to the remarks of Mr. Pennell and Mr. Sullivan, there must always be some amount of disappointment if a middleman came in. He could quite understand the feeling of disappointment an artist must have when he saw his drawing reproduced by wood engraving; he knew that well because he was an old wood engraver himself, and that was where the advantage of lithography came in over wood engraving.

The resolution of thanks was carried unanimously, and the meeting terminated.

THE SILK INDUSTRY OF SYRIA.

The silk industry of Syria has been from ancient times one of the country's principal sources of wealth, but owing to the lack of labour caused by the emigration of thousands of Syrian peasants to North and South America, Africa, and Australia every year, and to the fact that the lace-making industry took up the greater part of the time of the peasant women in the Lebanon, the amount of silk produced in late years has been considerably reduced. The eggs used for hatching silkworms are imported from the Department of Var, France. Syria formerly imported 270,000 to 300,000 boxes of eggs annually, and about 30,000 to 40,000 boxes of native eggs were produced, each box containing 25 grammes net weight of eggs, which yield from 55 to 82 lbs. of cocoons. The imports and production of eggs have been reduced yearly, and many proprietors of mulberry groves have been obliged to cut down or root up their mulberry trees and replace them with orange trees. When the season is good and the trees grow a considerable quantity of leaves, the demand for eggs is increased, according to the American Consul-General at Beirut, with a corresponding increase in price. The usual price of eggs per box is from two to three shillings, rising to eight shillings when the trees are in full foliage, with plenty of large juicy leaves. On the other hand, when the trees are bearing only a small amount of leaves, and these leaves are small and dry—which may happen if the spring is a very dry one—not all the eggs imported can be used, and a great many boxes have to be destroyed, with a consequent decrease in price. The eggs are shipped from France every year on or about August 15th, according to the climatic conditions, and reach Beirut about the first week in September. They are kept in Beirut until the end of October, and then are distributed among some of the monasteries in the Lebanon mountains, up near the snow-line, where they are kept in cool places until the hatching season, which begins in March. March 19th is the day fixed by all the silk producers for putting their eggs in incubators. After hatching they are tended in special huts made of rushes, reeds, grass, straw, and sticks until May 10th or May 15th, according to the climatic conditions, when the first worms, after having been fed liberally upon mulberry leaves, spin their cocoons The prices of cocoons always depend on the prices of raw silk at Lyons. In 1913 the prices ranged from 1*s*. to 1*s*. 2*d*. per lb., according to quality. There are over 150 factories in Syria that make a business of reeling the raw silk from the cocoons and selling it as thread or yarn. Some of these factories are always able to obtain specially good prices for their brands, which are known in Europe for their uniform fine quality. The other brands are classified as seconds and thirds. All the silk manufactured in Syria is made into skeins of a standard size used by French manufacturers of silk stuffs, and packed in bales weighing 220 lbs. each. Every year the silk merchants in Lyons open bank credits in favour of the silk manufacturers in Syria, and the silk manufacturers begin to draw on these credits at the beginning of the cocoon season, binding themselves to send a maximum quantity of silk to be sold for their accounts by the Lyons merchants. The total production of silk in Syria during 1913 was 770,000 lbs., and Beirut exported 550,000 lbs., which was about equal to the exportation in 1912. It is felt in many quarters that this industry has already reached its height, and that the production of silk will continue to fall off during the years to come.

THE SEA ROUTE BETWEEN ENGLAND AND NORTHERN SIBERIA.

Mr. Lied, whose commercial cruise in 1913, in company with Mr. Nansen, from Norway to the mouths of the Siberian rivers attracted so much attention and formed the subject of Mr. Nansen's work "Through Siberia," is now in Petrograd, making preparations for a third trip, and is expected to return to London in March next for the purpose of completing arrangements. Mr. Lied's second expedition took place last year just at the beginning of the war, but owing to the general excitement at the time it failed to attract much attention. Nevertheless it was particularly

successful. The ships that took part in the expedition were the two cargo steamers "Ragna" and "Skule," 2,450 and 1,850 tons respectively, four river steamers, 520 h.p. and 210 h.p., and two barges of 700 tons each. One of these contained two 150 h.p. river steamers, in pieces, to be put together on arrival in Siberia, and built by Thornycroft's firm.

The two cargo steamers had been chartered of the Siberian Steamship Manufacturing and Trading Company by the Russian Government for the conveyance of a full cargo of cement, iron and steel, to be delivered on the Yenisei for railway purposes. The river steamers and barges were bought by Mr. Lied in Germany, on account of the Russian Government, for future service on the Obi and the Yenisei. As they had to be specially strengthened for the voyage, and there was very little time to spare, the ships were registered in the German Lloyd's, and as a matter of formality had to make the voyage to Siberia under the German flag. This, of course, was before the war. The repairs were hurried through at Hamburg, and the ships and the river fleet left Cuxhaven on July 30th, just sixteen hours before the ships would have been confiscated by the German Government. They then proceeded under their own steam to Tromso. The two big cargo steamers were to load 15,000 barrels of cement in Aalborg, Denmark, and it was with the greatest difficulty that the ships succeeded in getting out thence on August 9th and making for Tromso. There Mr. Lied joined the expedition, and on August 16th a start was made for Siberia.

The expedition passed through the Kara Straits on August 24th, after having supplied the river fleet with coal from the big steamer off Vaigatch Island at the entrance of the Kara Sea. Here the expedition was troubled with fog and also with much ice. After three days, however, clear water appeared, and on August 30th the river steamer "Marie" (210 h.p.) and the barge "Skalk" were dropped at the mouth of the River Obi for their 3,000-mile journey up the river to Tomsk. With the rest of the fleet the expedition proceeded to Dickson Island, outside the mouth of the Yenisei, where they arrived on September 1st. Here they found the Russian rescue expedition, sent by the Government, in charge of Captain Sverdrup, to search for the lost Arctic expedition under Brusiloff and Rusanoff. Sverdrup's ship, the "Eclipse," was stranded on a rock. Mr. Lied's party discharged some of the cargo on to the decks of his steamers and towed the "Eclipse" off, after two days' work, after which she proceeded northwards, and should now be frozen in somewhere near Cape Chelyuskin. Mr. Lied's expedition then proceeded 180 miles up the Yenisei River to the appointed loading place, Nosonofski Ostrop, where the river fleet of sixteen vessels was awaiting them. Fourteen days were spent in loading and discharging, the return cargoes consisting of timber, hemp, flax, hides, etc., which were eventually landed safe and sound at Hartlepool. The river steamers on the Yenisei were taken over by the representatives of the Russian Government, and the whole fleet of twenty vessels returned to the interior for their 2,000-mile journey to Krasnoyarsk on the Siberian railway. The Lied expedition, with its two cargo steamers, the "Skule" and the "Ragna," commenced its return journey on September 19th. A quantity of ice was encountered north of White Island, and the temperature went down to 6° C. below zero. But the return journey was far more expeditious than the out journey, having occupied only eleven as against nineteen days, although very rough weather was experienced off the Norwegian coast.

The success of this second expedition has thus clearly established the practicability of the Siberian route from England, and its convenience at a time when the Baltic is impracticable is fully acknowledged in both Russian and English shipping circles.

SALT IN THE STATE OF OKLAHOMA.

By Chas. N. Gould, Ph.D.

Salt is present in many parts of the State of Oklahoma. Deep drilling in practically all parts of the State reveals the presence of salt water, contained usually in ledges of sandstones, and encountered at various depths. It is in the western counties, however, that the salt is the most abundant. This is the region of the red beds, of Permian age. The red beds consist largely of red shales and clays, with interstratified ledges of gypsum, dolomite, and sandstone. There are in this part of the State seven regions of salt plains or salt springs, points where a strong solution of salt brine escapes from the surface and flows away in streams.

The largest salt plain in Oklahoma is situated near the town of Cherokee, in eastern Alfalfa County. This plain is twelve miles long, north and south, and six miles wide, east and west. The surface is flat and level as a floor, and is covered for the greater part of the year with an incrustation of white salt crystals, so that from a distance the plain has the appearance of a snow field. During heavy rains these salt crystals are dissolved, and the flat surface of the plain is then a brownish red colour. There are no strong springs on this plain. However, a hole dug anywhere in the surface of the plain will be filled, within a few minutes, with a strong solution of salty brine. The water escaping from this plain flows into Salt Fork River and contaminates the stream.

At the base of the Gypsum Hills, which extend north and south across Western Oklahoma, there are three separate salt plains. Two of these are in the valley of Cimarron River, between Harper and Woods County. The largest of these plains occupies an area of about eight miles in length and two miles wide, lying along both sides of the river, and in a cove to the south of the stream. A number of springs of strong salt water occur in this cove.

The most noted salt plains in Oklahoma are in

northern Blaine County. The water at this place issues from two narrow canyons, which have been eroded in the Gypsum Hills. The streams from these two canyons unite and form Salt Creek, a tributary of Cimarron River.

Three salt plains are located in the south-western part of the State, two of them being in northern Harmon County and one in eastern Beckham County. The water in these springs issues from the base of the Greer Gypsum formations. The water from practically all of these springs is a saturated solution of salt brine. The amount of solid matter is so large that it is deposited on exposure to the air. Around many of the springs hummocks of salt have been built from the evaporation of the water, something after the manner of the deposits of sinter, in the vicinity of geysers.

For many years salt has been manufactured in a primitive way at these various plains, either by solar evaporation or by boiling in kettles. Some years ago an attempt was made at the Blaine County plain to produce salt in a commercial way. A mill was erected and was in successful operation for some months, when the property was purchased by parties interested in producing salt in an adjacent State, and shut down.

It has been estimated that the amount of salt water in western Oklahoma would produce one hundred cars of salt per day. At the present time none of this material is being utilised.

ARTS AND CRAFTS.

The Board of Trade Exhibition of German and Austrian Textiles.—The little exhibition of cotton and other fabrics of German and Austro-Hungarian manufacture held for two days at the end of last month, under the auspices of the Commercial Intelligence Department of the Board of Trade, at 32, Cheapside, was of hardly less interest to those interested in design for textile fabrics than to manufacturers. Quite a good collection of printed materials (mainly cotton and linen) had been arranged, and it was possible to gain some insight into the kind of German and Austrian work which has been coming into this country and apparently finding a market here. How far manufacturers (even should they so desire) will be able in the near future to produce work on German or Austrian lines depends, of course, in no small measure on the dye-stuffs available, the stocks of colour already on hand, and the success of the efforts to provide English substitutes for the German chemicals on which we have so largely, and, as it seems, so short-sightedly, depended. Presumably, however, while the primary object of the Board of Trade may have been to show manufacturers what is wanted at once, there lay behind it a desire to enable British makers to be ready and on the spot at that later date when the war should be over. In the main the German and Austrian designs have to be considered apart, for, whilst the German goods are for the most part purely commercial, those of Austrian origin appeal deliberately to a smaller and more consciously artistic public.

German Textile Designs.—It is apparent that the success of the German goods must be attributed to something other than their design. The patterns on the whole, whether cotton prints for furnishing purposes or simple dress and shirting patterns, were singularly lacking in distinction. The more ambitious work was up to a very fair technical standard; there were a few shadow effects, and many of the devices, such as the use of a slightly figured ground, of which our cotton printers have been making use, are part of the common stock of their German competitors. On the other hand, the designs were singularly dull and commonplace. Many of them were a German rendering of a French type of design which, though effective enough when treated with the Latin lightness of touch, is not well adapted to the heavier Teutonic handling. Others, again, are evidently inspired—to put it very mildly—from English sources. Indeed, in one or two of the most satisfactory patterns the source was so obvious that one was able to recall the exact pattern from which they were derived. But the English design had been printed on a cloth of a considerably better quality. That is probably the key to the whole situation. German goods of this class have presumably been bought over here simply and solely because they were cheap.

Austro-Hungarian Designs.—The Austro-Hungarian designs were on a totally different plane, and though the fact that they are very largely printed linens suggested that they have had a much more limited vogue, they were well worthy of study both for their own sake and because they suggest lines along which in the present crisis it might be possible for British producers to work. Not only those who have been in Austro-Hungary, but also those who have attentively studied the *Studio Year-Book*, have been conscious of the strides made in recent years in the Dual Monarchy in the direction of design. Many of the patterns have shown very obvious defects, some of them (especially those which have been most to the front in this country) have had marked affinities with what seems to some people rather frenzied futurist work, but for all that there has been a genuine movement towards direct, simple and individual design. The printing of these Austrian fabrics is often rather brutal. The outlines (of which great use is made) are frequently inordinately thick. The patterns sometimes suggest stencilling rather than printing. These things may perhaps be regarded as their defects, and against them must be put some undoubted qualities. The colour-schemes are new and very interesting, and it is surprising what light, fresh and distinguished effects have been obtained in simple patterns in which a thick black or other dark outline is the main feature, enclosing here and there touches of

brilliant colour. In some of the patterns shown at Cheapside the addition of a kind of half-tone grey colour helped towards a very satisfactory result. In a different field another notable piece of work has been done. This is the copying in printed cotton handkerchiefs and scarves, apparently intended for the East Indian market, of "battik" work. Whatever we may think of imitation as such, the colour effects of these things are some of them extremely good, and one wonders whether in work of a different class something analagous to the result obtained by the imitation of the running which takes place where the stopping-out wax has cracked might not be introduced with very satisfactory results.

It is to be hoped that British designers will profit by the very useful and inspiring collection of printed fabrics provided for their inspection by the Board of Trade. It is little exhibitions of this kind which ought to give them just that impetus which they want.

The Work of the Central School of Arts and Crafts.—A very wide field is usually covered by the exhibition of the work of students of the Central School of Arts and Crafts in Southampton Row, and the exhibits this year represent the principal crafts connected with book production, silversmithing and woodwork, as well as writing and illuminating, china painting, stained glass-work, embroidery, miniature painting, design. drawing and modelling. The show is always an event of considerable interest, for it enables the public to see what is being done at the School which, barring the Royal College of Art—which is after all a national rather than a local institution —is the most important of its kind in London. It is consciousness of this fact, perhaps, which leaves the visitor with a certain feeling of disappointment. The collection always includes a fair proportion of good work, but it is almost impossible not to regret that the best works shown have for the most part so little relation to the more important manufacturing industries of the country. The studies preparatory to design on view this year were certainly quite on right lines, but the more advanced original patterns, though in some respects more competent than those which used to be exhibited some years ago, were not particularly interesting, and there were very few of them. There was less woodwork than usual, but that may have been due in some measure to the war which has hit this pre-eminently London trade very hard indeed. The exhibits connected with book production—again an industry closely connected with London—were up to their usual standard. The printing showed that the students were being trained in the best principles of their trade, and some of the book illustration was very clever. The silversmithswork was, on the whole, less interesting, and a few of the objects shown suggested that the particular students responsible for them were more anxious to emphasise that their work was "handmade" than was quite consistent with the best art. The stained glass was in the main satisfactory, though some of it appeared to be rather too heavily painted. That may, however, have been due to the way it was exhibited. Stained glass is always difficult to judge out of its position, and at the Central School, at any rate by artificial light, only about a third of the examples shown were really well lit. A large number of the cases in the first room were devoted to embroidery, and the collection included also an elaborately embroidered altar frontal. Some of the stitchery was very interesting, and the little panel of St. John, with the face worked round and not straight, would have been quite satisfactory had the mouth been rather better managed. For the rest, while there was fine needlework in abundance, it seems a pity that the students who, it is to be hoped, are not quite all amateurs, are not encouraged to perfect themselves in a larger variety of methods. There is a comparatively coarse work which is by no means to be despised, and which allows needlewomen to attempt feats which could not be accomplished in finer stitchery. Further, appliqué is a kind of work which certainly merits some attention. The writing and illuminating were, as usual, up to a very high standard, though some of the more advanced students are a little inclined to over elaboration, and seem to forget that in an initial the thing of primary importance is the form of the letter itself. Unless that is right, added ornament is really wasted The students have learnt to choose their script and writing from a wider area than formerly. Many of the examples were very good, and the exhibits were far less after one model than they used to be. It is to be regretted that a school of this description should have been content to label so many of the works shown at an exhibition which was to last approximately a fortnight with untidy little bits of paper on which the exhibitors' names had been written apparently post haste by someone whose handwriting was not peculiarly beautiful or legible. It detracts from the effect of the work, and suggests a want of workmanlike method and order Finally, interesting as the exhibition was, its value would have very much increased had some indication been given of the status of the various students. It is difficult to estimate the real merit of work without knowing whether it is the output of a young trade scholar or a fully qualified workman, a casual amateur, or a teacher or student in training.

CORRESPONDENCE.

THE ECONOMIC DEVELOPMENT OF BRITISH EAST AFRICA AND UGANDA.

I listened with much interest to Major Leggett's paper on the Development of East Africa and Uganda, and I quite agree with his view that in looking to the future of East Africa the two

Protectorates must be dealt with together. As general manager of the Uganda Railway I had great opportunities of seeing the countries served by the railway, and by the steamers on the great lakes at the head of the Nile, and I endorse the views so ably expressed for the necessity of improved communications.

The development of traffic during the period when I was in East Africa was most promising, and called upon the capacity of the railway to the utmost. Much has already been done to improve the working of the railway and marine services, but as facilities are given, traffic increases and keeps the railway busy.

Survey parties are in the field for an extension of the railway to the west from Nakuru across the Uasin Gisho plateau, where available lands are already mostly taken up, and thence across the rich southern slopes of Mount Elgon to Mumias; and one hopes to see, in some ten years' time or perhaps a little more, rail-head carried right round the head of the lake and on into the Congo by the southern shores of Lake Albert and eventually junction with the railway from Stanleyville, and thus forge one more link in the chain of the Cape-to-Cairo Railway. The route would lie along the northern watershed of Lake Victoria, passing Mbale, the trade centre of a very rich cotton district, to Jinja, the eastern terminus of the Busoga Railway now connecting the Lakes Victoria and Kioga and serving a very large area under cotton. It is at Mbalo, I think, that any further extension northwards of the Cape-to-Cairo system should take off. I should like to note here that in my opinion the north and south lines will at no time carry any great traffic in mid and central Africa, but will act mostly as feeders to the east and west railways.

A bridge across the head of the Nile near the Ripon Falls will be an easy matter, and a line from Jinja to Kampala will serve a very rich country already under cultivation. From Kampala the line will run in an almost westerly direction to find a possible crossing of the waters flowing into the southern end of Lake Albert, and open out much good country that is already being broken up by settlers.

The east coast is the natural outlet for all traffic from around Lake Albert, and we must see that we put our communications and harbour in fit condition to deal with the produce offering. The natural features of Kilindini lend themselves to an excellent system of harbour construction, for which designs have already been got out. The country has now reached the producing stage, and after the war it will be essential that a big push be made with the improvement of communications. Any moneys spent to this end will rebound to the credit of the Empire in cheapening the cost of raw materials and in opening out fresh markets for home manufactures.

H. B. Taylor, M.Inst.C.E.

22, Cromwell Crescent, S.W.

GENERAL NOTES.

Tropical Agriculture.—The Proceedings of the Third International Congress of Tropical Agriculture, which have just been published (London: John Bale, Sons & Danielsson, 10s. net), form a substantial volume of over 400 pages. The volume is edited by the honorary secretaries of the Congress, which, it will be remembered, was held last June at the Imperial Institute. This was the first time the Congress had been held in London, and the result was most successful. More than one hundred and fifty papers, coming from authorities in fifty different countries, were presented to the Congress, and important discussions took place on several of the principal problems connected with tropical agriculture. Abstracts of the papers and full reports of the discussions are printed in the Proceedings, together with the address delivered by the president of the Congress, Professor Wyndham R. Dunstan, C.M.G., LL.D., F.R.S., Director of the Imperial Institute, and President of the International Association for Tropical Agriculture. Amongst the subjects dealt with in the Proceedings are Technical Education in Tropical Agriculture; Organisation of Agricultural Departments in Relation to Research; Agricultural Credit Banks and Co-operative Societies; Sanitation and Hygiene on Tropical Estates; Legislation against Plant Diseases and Pests; Fertility of Soils in the Tropics; Variation in Plantation Rubber; Cotton and Cotton Cultivation; Jute and Hemp Fibres; Cereals; Sugar; Cocoa; Tobacco; Oils and Oil Seeds.

Indigo Conference.—The Indian papers report that at a meeting of the Supreme Legislative Council on January 12th, Sir Robert Carlyle (Revenue Minister), replying to a question, said: "Natural indigo has undoubtedly suffered severely from competition with the synthetic product, and the Government of India are at present considering to what extent and in what manner assistance can be rendered to growers of indigo. To enable them to come to a decision it has been arranged to hold a conference shortly in Delhi."

Increase of Shipping at Rotterdam.—The number of vessels entered at the port of Rotterdam in 1913 was 10,527, with a net tonnage of 13,047,000 tons, against 10,477 with a net tonnage of 12,360,000 in 1912. The average tonnage per ship increased from 1,179 in 1912 to 1,239 in 1913, which increase was more than in any previous year. In this connection attention is called to a statement made by the president of the Hamburg Chamber of Commerce, in which he admitted that although Hamburg is still ahead of Rotterdam in tonnage of ships, but with an annually decreasing percentage, Rotterdam is already ahead of Hamburg as regards the quantity of goods handled. The inland shipping increased from

158,673 ships, with a tonnage of 29,254,000 in 1912, to 161,948 ships with a tonnage of 30,486,000 in 1913. The number of ships arriving at New Waterway (Rotterdam) in 1912 was 11,317 of 13,473,000 net tons, and 11,448 ships of 13,915,000 tons in 1913. In 1912 there arrived at Antwerp 6,978 vessels of 11,697,000 tons, and in 1913, 7,056 vessels of 12,022,000 tons. This shows that the New Waterway had 4,387 vessels, with 1,893,000 registered tons more than Antwerp.

Coconut-water as a Rubber Coagulant.—An important discovery has just been made in the use of coconut-water as a rubber coagulant, according to the United States Consul at Colombo. Millions of gallons of coconut-water which now runs to waste on estates in copra drying and desiccation mills, can be utilised as a profitable by-product, besides producing a superior coagulant in making rubber. Details of the process are not now available, but it is understood that the coconut-water is allowed to ferment for four or five days, after which it can be used immediately for coagulating latex. One to two ounces of the fermented liquid will coagulate one pint of pure latex. It is said to produce a better rubber than that procured from the present method of using crude acetic acid, especially so far as colour goes, and clearer than that obtained from the cocoa-fermentation acid treatment. Experiments are being carried on to determine how long the liquid will keep, and how practicable it will be to transport it from the coconut plantation to the rubber estates.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock (except where otherwise announced):—

February 17. — Arthur Wilcock, "The Decorative Textile Industries and the Designer's Relation thereto." Sir Charles Waldstein, Litt.D., Ph.D., will preside.

February 24.—W. J. Ashley, M.A., M.Com., Ph.D., Professor of Commerce in the University of Birmingham, "The Economics of the War." The Right Hon. Sir George Houston Reid, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, will preside.

March 3, at 4.30 p.m. — William Poel, "Shakespeare's Profession." Sir Squire Bancroft will preside.

March 10.—J. W. Gordon, "Patent Law Reform and the War." Dugald Clerk, D.Sc., F.R.S., will preside.

March 17. — H. M. Thornton, "The Industrial Uses of Coal Gas."

March 24, at 4.30 p.m.—Lady Lugard, "The Work of the War Refugees' Committee."

Indian Section.

Thursday afternoons:—

March 18, at 4.30 p.m. — Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army."

April 15, at 5 p.m. — Perceval Landon, "Basra and the Shatt-ul-Arab." The Right Hon. Earl Curzon of Kedleston, G.C.S.I., G.C.I.E., will preside.

May 13, at 4.30 p.m.—M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March 2.—David Lindsay (Leader of the Elder Scientific Exploration Expedition, etc.), "The Northern Territory of Australia: Past, Present, and Future."

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced:—

T. Thorne Baker, "The Industrial Uses of Radium."

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. Hulme, "Patent Law."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

A. S. E. Ackermann, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., "On an Economical and Smokeless Grate, and on the Measurement of the Efficiency of Open Grates."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

M. H. Baillie Scott, "House Building—Past and Present." Three Lectures.
March 15, 22, 29.

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.
April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evenings, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 15.—*Petrol.* Its production and properties—The composition and grades of petrol—Transportation, storage, and distribution—The dangers of petrol—Calorific value, and how far it is a basis for comparison—The properties essential in a good motor fuel—Vapour tension and fractionation as indicators of the value of a petrol—Supply and demand.

LECTURE II.—FEBRUARY 22.—*Petrol Substitutes.* (*a*) Definite compounds—Benzol and alcohol. (*b*) Mixtures—How far mixtures of heavier grades of petroleum with spirit can be used. (*c*) The "cracking" of heavier fractions of petroleum into spirit—The researches upon which such processes are based, and their teaching.

LECTURE III.—MARCH 1.—"*Cracked*" *Spirits.* The effect of degree of temperature used—The use of water or steam—Surface action and its supposed effect—Processes in use—The utilisation of gases in solution to increase vapour tension—The steam engine *versus* the internal-combustion engine for motor traction—Conclusions.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Fothergill Lecture.) Professor Vivian B. Lewes, "Motor Fuels." (Lecture I.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. D. Gath Whitley, "Traces of a Religious Belief of Primeval Man."

Electrical Engineers, Institution of (Local Section), Mining Institute, Newcastle, 7.30 p.m. Discussion on "Wiring."

Surveyors' Institution, 12, Great George-street, S.W., 7 p.m. (Junior Meeting.) Mr. W. A. Kirby, "The Cultivation and Resources of the Huntingdonshire Fen Lands."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. A. N. Prentice, "Architectural Sculpture in Spain."

East India Association, Caxton Hall, Westminster, 4 p.m. The Earl of Ronaldshay, "Impressions of India."

TUESDAY, FEBRUARY 16...Statistical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Dr. E. C. Snow, "On the Magnitude of the Population of England and Wales available for Emigration."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. W. Thorpe, "The Development and Design of Lighting Fixtures in Relation to Architecture and Interior Decoration."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Muscle in the Service of Nerve." (Lecture IV.)

Engineers and Shipbuilders of Scotland, Institution of, Rankine Hall, Glasgow, 8 p.m.

WEDNESDAY, FEBRUARY 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. Wilcock, "The Decorative Textile Industries and the Designer's Relation thereto."

Meteorological Society, at the Surveyors' Institution, 12, Great George-street, S.W., 7.30 p.m. 1. Mr. A. E. M. Geddes, "Observations of the Upper Atmosphere at Aberdeen by means of Pilot Balloons." 2. Mr. V. G. Anderson, "The Influence of Weather Conditions upon the amounts of Nitric Acid and of Nitrous Acid in the Rainfall at Melbourne, Australia."

Microscopical Society, 20, Hanover-square, S.W., 8 p.m. Presidential Address by Professor G. Sims Woodhead, "Some of the Micro-biological Problems of the Present War."

Electrical Engineers, Institution of (Students' Section), Victoria-embankment, W.C., 7.45 p.m. Mr. A. Arnold, "Modern Power-house Condensing-Plant."

THURSDAY, FEBRUARY 18...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. A. Hall, "The 'Cracking' of Oils, with a view to obtaining Motor Spirit and other Products."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. Mr. H. Wager, "The Action of Light upon Chlorophyll."

University of London, University College, W.C., 5.30 p.m. Monsieur C. Poupeye, "Belgian Art." (Lecture V.)

Chemical Society, Burlington House, W., 8.30 p.m. 1. Messrs. J. D. Canwood and W. E. S. Turner, "The dielectric constants of some organic solvents at their melting or boiling points." 2. Mr. F. D. Chattaway, "The preparation of allyl alcohol." 3. Mr. A. Parker, "The velocities of flame in mixtures of methane and air." (Part II.)

Royal Institution, Albemarle street, W., 3 p.m. Dr. P. Chalmers Mitchell, "Zoological Studies: War Evolution; Struggle of Species." (Lecture II.)

Camera Club, 17, John street, Adelphi, W.C., 8.30 p.m. Mr. C. E. Dawson, "The Photo-Play and its Possibilities."

Historical Society, 22, Russell-square, W.C., 5 p.m. Anniversary Meeting.

Numismatic Society, 22, Albemarle street, W., 6 p.m. Mr. H. Symonds, "The Irish Coinage of Henry VIII. and Edward VI."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. T. A. Watson, "Economy in Reinforced Concrete Construction."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 8 p.m.

FRIDAY, FEBRUARY 19...Royal Institution, Albemarle-street, W., 9 p.m. Professor H. E. Armstrong, "The Visit of the British Association to Australia."

Sanitary Institute, Manchester, 7 p.m. 1. Mr. S. S. Platt, "The Construction of Sewers." 2. Mr. H. Dryland, "Housing from a Sanitary Inspector's Standpoint."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 8 p.m. Mr. A. E. L. Chorlton, "Convertible Combustion Engines."

SATURDAY, FEBRUARY 20...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Recent Researches on Atoms and Ions." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,248. VOL. LXIII.

FRIDAY, FEBRUARY 19, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 22nd, 8 p.m. (Fothergill Lecture.) PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." (Lecture II.)

WEDNESDAY, FEBRUARY 24th, 8 p.m. (Ordinary Meeting.) W. J. ASHLEY, M.A., M.Com., Ph.D., Professor of Commerce in the University of Birmingham, "The Economic Position of Germany." The RIGHT HON. SIR GEORGE HOUSTON REID, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

At the last meeting of the Council, on Monday, the 15th inst., the HON. RICHARD CLERE PARSONS, M.A., was elected a member of the Council and Vice-President of the Society, in place of the late Sir Owen Roberts, D.C.L., LL.D.

FOTHERGILL LECTURES.

On Monday evening, February 15th, PROFESSOR VIVIAN B. LEWES, F.I.C., delivered the first lecture of his course on "Motor Fuel."

The lectures will be published in the *Journal* during the summer recess.

CANTOR LECTURES.

The Cantor Lectures on "The History and Practice of the Art of Printing," by R. A. PEDDIE, Librarian of the St. Bride Foundation Typographical Library, have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor and Howard Lectures which have been published separately, and are still on sale, can also be obtained on application.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, February 2nd, 1915; The RIGHT HON. LORD DESBOROUGH, K.C.V.O., and afterwards SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, in the chair.

THE CHAIRMAN, in opening the proceedings, said he very much regretted that he would be unable to occupy the chair after he had introduced the reader of the paper to the meeting, as the question of the Volunteer Defence Force, in which he was greatly interested, might be raised in the House of Lords, and he desired to be present. The author had written papers and delivered lectures on West Indian and cognate subjects. He was a delegate to the Agricultural Conference in Trinidad in 1912; was the West Indian Committee's representative at Ottawa during the Canadian-West Indian Reciprocity Conference in the same year; had been a West Indian delegate at three successive Triennial Congresses of the Chambers of Commerce of the Empire, and was engaged in the formation of an Association of Chambers of the West Indies. As those present might be aware, there was an Association of the Chambers of Commerce of the British Empire, which met every three years, the next meeting being due to be held at Ottawa in September, but in all probability, owing to the war, the meeting would be postponed for a year. That adjournment would give the author an opportunity of consolidating the

Chambers of Commerce in the West Indies, and enable him, as their representative, to speak with authority at the Congress whenever it was held. He hoped the Congress would apply itself, under the two mottoes of "Unity in Commerce" and "Unity in Defence," to the discussion of affairs of inter-Empire commerce in a practical manner, and that the results of those deliberations would be to the lasting benefit of the trade of the British Empire.

The chair was then vacated by LORD DESBOROUGH, and taken for the remainder of the meeting by SIR THOMAS HOLDICH.

The paper read was—

SUGAR AND THE WAR.

By EDWARD R. DAVSON.

Sugar is popularly considered to be one of the most domestic of articles, and yet it may be questioned whether any other product has been so much affected by politics and war. Certainly it cannot claim to have precipitated a war like tea at Boston in 1773, but it is the only commodity which doubled in price when the present war was declared, the only one for which a convention of European Powers exists, and the one selected by the Government to experiment with in State trading—a step which some may think one of the most interesting in the industrial history of this country.

It may be as well to refer to the position which sugar occupied in and after our last European war, viz., the Napoleonic struggles at the beginning of the nineteenth century, when commercial sugar was entirely produced from the sugar cane, and the West Indies and South America were responsible for supplying the greater part of the world's markets.

During that war a situation arose of which we have had a similar, though slighter, experience at the beginning of the present war. The enemy's ships—the "Emdens" of history—scoured the seas and sank many sugar-laden vessels, and as a beneficent Government had not then instituted a War Risk Insurance the loss fell entirely upon the sugar-planters. England, however, established her supremacy at Trafalgar in 1805, and the enemy's warships disappeared; but in 1806 a decree was issued from Berlin, which was then occupied by the French, that all trade communication with England was forbidden. This was known as the Continental system. It dealt a disastrous blow to the cane-sugar industry, but, as is ofttimes the case, the restriction of commerce recoiled upon its originator, and Napoleon found that the lack of sugar from which the French were suffering was most inconvenient.

Some years before this, however—in 1747—one Marggraf announced to the Royal Academy of Berlin that sugar could be made from beetroot, and in 1800 the King of Prussia started growing beet in Silesia in order to obtain sugar from it. This discovery seemed to Napoleon to afford him the solution to his trouble, and he also had a beet estate planted, and established four schools where sugar manufacture might be taught.

Thus began the great European beet industry, and also the rivalry between beet and cane sugar which has continued to the present day, and which, as I have shown, originated from war.

Germany gave large subsidies to beetroot, and therefore beet flourished and cane suffered. Then the Continental system was abolished, and once again cane flourished while beet suffered. Then slavery was abolished in the Colonies, and again the positions were reversed. Later on there began to grow up in Germany, Austria and France a development of the granting of subsidies in the system of Government bounties for the export of beet, which gave a tremendous impetus to the industry; so much so that, while in 1870 the production of beet was 952,000 tons, thirty-two years later—that is, in 1902—it had reached no less a figure than 6,180,000 tons.

The situation was a serious one for our colonial sugar industry. There could only have been one end—its extinction; and eventually the British Government realised this in 1902. So, thanks mainly to Mr. Chamberlain, at that time Colonial Secretary, this country informed the Powers that unless bounties were abolished she would prohibit the import of all sugar which received them. This resulted in the Brussels Convention, by which all the Powers agreed to abolish their bounties, except Russia, which came in later, in 1907, on special terms allowing the continuance of its bounties but restricting its exports; and from that time cane sugar was freed from this menace against its expansion.

This, then, was the position at the outbreak of the present war: beet sugar produced 8,910,000 tons, while cane sugar produced 9,610,000 tons, showing that cane had regained the supremacy in production which it had lost before 1902.

Most of the cane sugar, however, went to the Western world, and of the 1,970,000 tons which this country imported in 1913, 1,600,000 was

beet from Europe, and only 370,000 came from cane-growing countries. Of this 1,600,000 tons, 1,200,000 came from Germany and Austria, and therefore we arrive at the important fact that 75 per cent. of our Continental imports, or over 60 per cent. of our total imports, amounting in value to £15,000,000, came last year from the two countries with which we are at present at war.

Fourteen years ago I pointed out in an article in a review the large extent to which England was dependent on Germany for her sugar supply, and I further suggested that the German agricultural districts were looked on as the chief recruiting ground of the army, and that the bounties given so many years had possibly a military as well as a political significance.

You will find that General Bernhardi, in his book "Germany and the Next War," discusses this question of rural population, and states that while large sections of the population in the great cities are absolutely hostile to the army, "the country folk, from a military point of view, form the backbone of the nation."

Germany had a production of 2,738,000 tons and Austria one of 1,710,000 tons in 1913. Of this Germany exported 1,104,000 tons, of which 894,150 tons (or 81 per cent.) came to England, while Austria exported 1,056,000 tons, of which 324,000 tons (or 30 per cent.) were shipped to this country.

It is calculated from these figures that about 700,000 acres in Germany and Austria combined are devoted annually to the growing of beet for the English market, and that this industry must support not less than 350,000 men of serviceable age. One must not carry the argument too far, as these men, if not engaged in growing beet for us, would undoubtedly be doing something else. But one may be allowed to assume that by paying them this £15,000,000 annually we have been of great benefit to what Bernhardi calls "the backbone of the nation from a military point of view."

Now let us see what happened last August. Germany, Austria, Russia, France and Belgium, with a collective production of 7¼ million tons, or 40 per cent. of the world's sugar production, were at war. It was, therefore, assumed that there would be a shortage of this amount in the world's supply; but actually 4¾ million of this was produced for internal consumption, leaving 2½ million as the shortage to the outside world —that is, supposing that no sugar at all was exported. Latest statistics show that the shortage in Europe, in spite of the war, will be less than a million tons; but, as exports are largely curtailed, we may for our purposes put the deficiency to the outside world at two million tons. In 1911 a drought occurred in Europe, and there was a resultant shortage of this same amount of two million tons out of the world's production. On that occasion the price rose by 80 per cent. in England and America. In August last, therefore, the price might have been expected to rise to the same extent; but actually it rose by 140 per cent. On precedent, therefore, the price rose to an extravagant and unjustifiable height, and, as it was based on a false premiss, the presumption was that it would fall again. This has actually happened in America. Nevertheless the situation in August was a serious one; the retail price was rapidly advancing, and, considering the circumstances, there appeared to be great opportunity for wealthy speculators to try to effect a corner in sugar against this country.

The British Government thereupon decided to go into the sugar business. It proceeded to buy up a sufficient supply of sugar, amounting to nearly a million tons, to make certain of its wants for the ensuing six months, and it paid for this sugar, not the extravagant price of the moment, but a price approximating to the precedent of 1911. Once these supplies were obtained and England ceased to be a buyer in the world's markets, the reaction in price to which I have referred began. This reaction was aided by the fact that Austria commenced to offer some of its crop in outside markets. The result of this, in turn, was that cheaper sugars were offered in the English market, and the Government, presumably in order that it should not suffer through these cheaper and possibly enemy's sugars appearing in competition with its own, thereupon prohibited the importation of practically all sugar into this country except what it had already purchased.

Critics of the Government's policy have pointed to this fact, and have declared that the Government would have been wiser to have left the sugar market to take its natural course; but I do not think that one can offer any criticisms until the transaction is closed, and until it can be proved, if that is possible, by studying the psychological conditions and the possibilities of corners in August last, and by analysing the course of prices since then, whether the Government has been wise or otherwise.

There remains the larger question of whether a Government should ever undertake commercial

trading, but this does not come within the scope of this paper. Broadly speaking, however, one may say that the best safeguard against such a necessity lies in a wise provision which may prevent one from ever again becoming dependent for any necessary of life to the extent of 60 per cent. of one's wants on any foreign country or group of countries.

There is another point to which I would refer in this connection. The Government bought from Java and Cuba at a natural price--that is, a price fixed by the free bargaining of buyer and seller. With the British Colonies the procedure was different. The Government practically "commandeered" the sugar in these Colonies, and announced the price which it intended to pay. This price was not always equal to that paid to others, and it was undoubtedly lower than that at the time obtainable in the case of the West Indies by selling to Canada, and in the case of Mauritius by selling to India and this country. The Colonies made little demur; the nation wanted sugar, and they put patriotism before price and accepted what was offered. But this suggests an interesting thought. By "commandeering" the crops of the Colonial producers the Government has established the theory that producers of a commodity in the Colonies are liable to have that commodity taken over by the Mother Country in time of need. This is no bad theory, but it seems to require the corollary that to ensure such sources of supply in time of war we must not neglect them in time of peace.

There is still another point. The Government's action simply caused a displacement of sugar; it did not increase the sources of supply from which it could draw by one ton—that is to say, its solution of the problem was an emergency, and not a final one, for it consisted in taking other people's sugar and not in providing an increased supply.

Now in 1905 a Royal Commission was appointed with these terms of reference :—

"To enquire into the conditions affecting the importation of food and raw material into the United Kingdom in time of war, and to advise whether it is desirable to take any measure in addition to the maintenance of a strong fleet, by which such supplies can be better secured and violent fluctuations avoided."

The terms were wide, but the Commission confined itself for the most part to the consideration of the important question of wheat. Some of its findings, however, were interesting, as bearing on the subject we are considering to-day. For instance, it says :—

"In the Civil War of America supplies of cotton from the United States practically stopped. Other sources of supply were drawn on, but our total imports, which were 1,257,000,000 lbs. in 1861, fell in 1862 to 524,000,000 lbs."

That is to say, one foreign country supplied nearly 60 per cent. of our cotton, and when it went to war—although we were not concerned in this—we were cut off from its supply.

Again, the Commission says :—

"We regard the present variety of sources from which our supplies are drawn as likely to contribute to our advantage in time of war . . . Instead of deriving 62 per cent. of our total imports of wheat and flour from a single source, we are at the present time drawing our main supplies from four countries in widely different parts of the world."

Now this condemnation of our former dependence on 60 per cent. of our cotton and on 60 per cent. of our wheat and flour from a single foreign source is interesting, since, as I have shown, we are at present dependent on 60 per cent. of our sugar supply from what, as far as this war is concerned, we may call "a single foreign source," and I think we may fairly consider the remarks quoted as applying with equal force to sugar.

What, then, is the remedy to be? Surely that encouragement should be given to the growth of sugar within the Empire, not from any one source, but, as the Commission has it, from a variety of sources. It is true the Commission does not say that products should primarily be grown within the British Empire, but the friends of to-day may be the enemies of to-morrow. This war with Germany and Austria has meant the cutting off of 60 per cent. of our sugar supplies. War with Holland would mean the loss of Java as a source of supply. War with the United States might mean the cutting off of Cuba. We are told that we depend on our Fleet to maintain our food supply. This is true, as long as the supply is waiting to be shipped; but if foreign countries do not choose to sell us their products, no fleet can bring them to our shores. It is different with our Colonies. Their products are always at our hand, and the Government, as I have said, has claimed to have as much right to control the sugar of Demerara and Mauritius as the hayricks and horses of the British farmer. That is why I venture to say that our sugar supply should be primarily grown within the Empire.

Now let us see where these sources of supply may be looked for. There is, first of all, our own country. For some years past those interested in the agricultural development of our land have pointed out that in the flat lands of East Anglia we have a soil very similar to that on which the heaviest Dutch crops are grown, and they have argued that if sugar can be grown on such lands in other countries, there is no reason why it should not be grown on similar lands in England. Such an industry would supply work both for agricultural and factory hands, it would bring into beneficial cultivation lands now lying untilled, and it would improve the land which is already in cultivation.

In 1914 there were 341 beet factories in Germany, 209 in France, 294 in Russia, 201 in Austria-Hungary, 68 in Belgium, 39 in Italy, 32 in Spain, 27 in Holland, 21 in Sweden, 9 in Denmark, and also factories in Roumania, Bulgaria and other smaller countries. Yet in England, with its annual consumption of two million tons, there is only one small factory recently established at Cantley, in Norfolk, the establishment of which may be considered due to the agitation to which I have referred that beetroot should be grown in England. Actually it was erected by an Anglo-Dutch company, which placed its bonds on the English money market, and with part of the proceeds of these built the factory. Beetroot was planted in the neighbourhood by farmers, and as an import duty on sugar of 1*s.* 10*d.* per cwt. existed and still exists, the question of Excise immediately arose. The Government, however, recognised the need of giving encouragement to a new industry, and they have rightly, as I think, abstained from placing an Excise duty upon it, so that it receives a protection in the home market of the amount which I have named. Unfortunately, however, it cannot be said that the Cantley factory has so far proved as successful as was hoped. Difficulties have been experienced which I need not enter upon, but, broadly speaking, one may deduce this fact: A beet factory, to be worked successfully, must be worked on a large scale; the larger it is the more profitable it is, because the working costs per ton diminish, subject to the reservation that there is a certain distance beyond which it does not pay to transport the roots; but no capitalists are inclined to subscribe the capital and working costs of such a factory—say, £250,000 to handle 100,000 tons of roots—unless they are certain that these roots are going to be grown, and that the price of sugar will be sufficiently remunerative. On the other hand, no farmer is going to embark on a new industry and plant up many acres in beetroot unless he is assured that the factory is there to receive them, and is likely to continue to be there in the future, and that he also will receive a remunerative price. Therefore, one reaches an *impasse*, and it is suggested that it could be got over by the Government granting or guaranteeing whatever amount is required for the establishment of such a factory as I have indicated; and should such a factory prove the success anticipated, it is confidently hoped that other factories will spring up around the country, the capital for which would be subscribed from private sources. It may be said that a quarter of a million is a large sum for a Government to guarantee to a new industry, but such an outlay would be infinitesimal as compared with the extra cost of sugar in time of European drought or war (for in the three years 1904, 1911, and 1914 these have cost us over 20 million pounds), and it may well be regarded as a form of insurance.

Now let us look at our sources of supply within the Empire, of which the West Indies and British Guiana deserve pride of place, as being our oldest sugar-producing Colonies. In 1887 these Colonies produced 343,000 tons, which, with modern methods of manufacture, would represent about 450,000. Last year they produced 191,000 tons. Jamaica alone once produced 80,000 tons; it now produces 15,000 tons. The Windward and Leeward Islands in 1887 produced 45,000 tons, while last year they produced only 24,000. Now, why is there this serious falling-off in the production of the West Indies? One reason undoubtedly is that they have learnt to grow a variety of products instead of being entirely dependent on sugar. But this alone does not account for the diminution of the West Indian crops. It is largely due to the Continental bounty system to which I have referred, and when this system was abolished the predominance which the State-nurtured beet industry had established, owing to its scientific development and the considerable protection still left to it by the Convention, made it impossible for the cane industry, with its exiguous resources and injured credit, to recapture the markets and so restore the industry to its former size. So we find the West Indies dotted with derelict factories and sugar lands given over to catch crops, the restoration of which depends not

so much on the West Indian planter as on the British nation.

In discussing this subject one must refer to India—which has a normal production of 2,500,000 tons—that is, with Cuba, the largest sugar producing country in the world. India, however, is not likely to become an exporting country for many years, as, in spite of its large production, it imports about three quarters of a million tons.

A large part of this comes from Mauritius; and here, on the other hand, we find possibilities of an extension of the sugar industry. The present production of Mauritius is 225,000 tons, and there is at present a Government scheme of irrigation under consideration which, when carried through, will considerably extend the land available for cultivation. Difficulties exist over the matter, but prospects of a remunerative price for produce in the future would undoubtedly tend to smooth these away. Again, it cannot be said that the majority of the factories of Mauritius have got the most modern equipment of machinery, and here again, with the introduction of the latest scientific inventions, there is every likelihood that a considerably increased output could be obtained.

If we turn to the mainland of Africa, we find Cape Colony and Natal, in which a flourishing sugar industry already exists, and is capable of much development; but there is a growing demand for sugar in the country, and it may be presumed that as the sugar production of these Colonies increases it will be met by an increasing consumption, and, therefore, little reliance can be placed upon the possibilities of these countries supplying the wants of the British market.

On the other hand, we have West Africa and Southern Nigeria, the coastal parts of which are eminently suited for sugar-growing; and the same remark applies to British East Africa, where the low-lying front lands are similar to those of Demerara, and where vast crops could be grown if only the growers were assured of a market. Nor must we omit to mention Egypt, where the extensive irrigation works carried out both in Egypt and the Sudan make possible the further development of its sugar industry.

There are various other places within the Empire where sugar can also be grown or developed; but I think I have indicated enough to show that we could at any rate grow a considerable part of the commodity which we now import so largely from foreign countries; for be it remembered that the production for which we are looking for an alternative source of supply covers an annual acreage of a million acres, and if we regard the vast territories of our tropical Empire, much of which is still awaiting the hand of the cultivator, it does not seem that the proposition is a very large or a very difficult one.

But in order to accomplish this aim some encouragement must be given to Colonial growers, and they point to the fact that they are differentiated against in the English market, and that while the English beet industry receives a protection of 1*s.* 10*d.* per cwt., they have to pay duty of that amount.

By the terms of the Brussels Convention all signatory countries are allowed a protection on sugar imports of 2*s.* 6*d.* per cwt., or about ¼*d.* per lb., and this every country has availed itself of except Holland and ourselves. Supposing, then, that, as is probable, our duty continues, or is increased, I think that if for a term of years it was decided that it should not be imposed, not only on home but also on Colonial sugar, we should find a very large increase in the sugar production of the Empire. Remember that this is not a suggestion to increase the price, but only to waive the duty on a very small percentage. It is true that as the percentage grew there would be a continual decrease of revenue; but one may hope that there would also be a continually decreasing need for taxation, so that this country would not suffer.

It is true, too, that there is what one may consider rather an unfortunate clause in the Brussels Convention, that is—

> "The Government of Great Britain declares as an exceptional measure and reserving in principle entire liberty of action as regards the fiscal relations between the United Kingdom and its Colonies and possessions, that during the continuance of the Convention no preference will be granted in the United Kingdom to Colonial sugar as against sugar from the contracting States."

But considering the freedom of action which the Government has since claimed in respect of various matters connected with the Convention, and considering our present relations with some of the signatories, I think that the time has arrived—that is, if the Convention is not dissolved after the war—when this country should avail itself of this "liberty of action," and say to the world that its Empire is a single unit and that it can brook no foreign interference in domestic matters relating to itself and its Colonies.

But while giving to producers the opportunity of a remunerative price, on which I have touched, there is also the need of guaranteeing that opportunity for a definite period of time.

During the Canada-West Indian Reciprocity Conference in Ottawa in 1912, I could not help being impressed by the way in which both parties realised that a preferential tariff was not in itself sufficient to develop trade, but that this tariff must hold good for a sufficient time to allow capital to be invested with security in the trades and industries which it was desired to develop.

Hence the signing of an agreement by which Canada and the West Indies gave a preferential tariff to each other for a term of ten years, and incidentally one may note that the West Indies, dependent as they were on their tariff for revenue and small as their exchequers were, also gave a preferential duty on English goods for this period.

These measures, then, the absence of Excise on and State encouragement to home-grown beet and the waiving of duty on Colonial sugar, for the same term as some of the Colonies have given us a preference over Germany on our manufactures would, I believe, bring about the desired result. And let me point out that such a consummation would also mean the extension of the British sugar-refining industry. For of the 1,600,000 tons last year imported into England, 928,000 tons were refined sugar; and there is no reason why a large portion of this should not be refined in this country.

What, then, is actually being done? Nothing, I am afraid.

It is true that the Board of Trade has recently started a campaign to capture German trade, and Chambers of Commerce have taken up the matter with commendable zeal; but so far there is little sign of one of the most important items of the propaganda receiving the study it deserves. It is true, too, that a Royal Commission on Sugar Supplies was appointed in August to deal with the State purchases of sugar to which I have referred, and its terms of reference include these: "To inquire into the supply of sugar in the United Kingdom . . . and generally to take such steps as may seem desirable for maintaining the supply."

But I do not think it is meant to extend its scope to a question of such Imperial importance. If official investigation is necessary to inquire into these matters, I venture to suggest that a reappointment, even to a limited extent, of the Royal Commission of 1905 on Food Stuffs in time of War would carry weight and probably achieve a beneficial result.

Political economy in the past has concerned itself mainly with the rival benefits or drawbacks of Free Trade and Protection in reference to international trading. I think, however, that there must now be added to these two theories of trade a third one in the need of preserving our food supplies in time of war; and surely this war problem is a far greater and a far more urgent one than any problems of peace; for in peace time the difference between a right and a wrong course of action in trade will certainly mean a difference in the amount of wealth which may be obtained, but in war time this difference may mean the starving out of this country and the extinction of the Empire.

Already the old order changeth, and Governments of whatever party they may be are showing a greater sympathy with the need of assisting commerce. We are beginning to recognise, as Germany has long recognised, that trade is a part of the fighting machine to be jealously fostered and safeguarded by the nation, and only less important than the fighting forces themselves. Therefore, one may hope that this question may be treated, not so much in accordance with the rules of text-books and traditions and creeds, as in accordance with the needs of this country which emergency calls forth.

In conclusion, let us remember that our Colonies will surely say this to us: "For years past you have paid these millions of money for a product which we could grow as well to those who are now your enemies. For years past you have thus helped to fill their war chests and supply their armies. And now, when they make war against you, we let you seize our crops, we give you what we can in money and in kind, and we send you our sons to fight against a common foe. What is to happen after the war? Are you going to let the unity of the Empire be a reality for us, or are you going to give your custom again to our enemies, and so once more help them to prosperity at our expense?"

That is the question which they will surely ask, and I hope that in reply a prompt and satisfactory decision may be reached; and if by this decision such remedies as those which I have ventured to indicate to-day can be adopted, I think we shall find that, in increasing the sources of our sugar supply, we shall be increasing the prosperity of our kith and kin abroad, and that by protecting our producers in time of peace we shall be protecting our consumers in time of war.

DISCUSSION.

Mr. C. Sandbach Parker, in opening the discussion, said the subject of the paper was of particular interest to him, as during the whole of his business life he had been engaged in the production of sugar in the West Indies, and for the last twenty years he had devoted the closest possible study to the conditions affecting the production of sugar all over the world. The question before the country at the present time was whether the policy that had been adopted in the past was a wise one in its own interests, and if it was not whether it was prepared to alter it. It seemed to him that anybody who had read the Report of the Royal Commission on Food Supplies, and who had noticed the effect of the cutting off of a large proportion of this country's supplies by the war, must be struck by the fact that in the effort to support what had justly been called a fetish, *i.e.*, to allow trade to pursue absolutely its own course, the country had got into a position where, unless the Government had stepped in to protect the sugar consumer, it might have been face to face with the most severe famine of sugar that had ever been known in the history of the world. The people who were most interested at the present juncture, in considering the question in all its aspects, were those who relied upon sugar as a raw material for their industries in this country, such as the refining industry, the confectionery industry, and numerous other sugar-using industries. It was for them to make up their minds whether they were prepared to see the country go back to the old position of practically entire dependence on foreign supplies, or whether they desired that some effort should be made to make this country less dependent for its supplies on foreign sources, especially when they knew perfectly well that the sugar which was required for this country could be produced within the Empire, given security of market, as cheaply as it was produced anywhere in the world at the present time. Some people might say that the West Indies could not produce all the sugar that was required, but those were not the only Colonies in which it was possible to grow sugar. The author and himself were proud of their connection with the West Indies during the most troublous years of their history, and he hoped they had gone through the worst times, so far as the sugar industry in those Colonies was concerned, that would ever occur; they looked forward to better times. Whereas years ago the common complaint of the sugar-using industries was that the West Indies wanted protection, and that it would pay this country better to give them a big bounty, or pay them so much a year, than to go on buying its sugar abroad, the position was totally different at the present time. There was now a safe market for West Indian sugar owing to the arrangement to which the author had referred that had been made with Canada, and, having that market secure, as West Indians they were not so dependent on the English market. Therefore it was for the consumers in this market to make up their minds whether they wished to develop the industry of the British Empire, and if so what steps they were prepared to take to bring it about. The author had proposed a remedy practically on the same lines as the one proposed by himself in an article he wrote on the subject two months ago, namely, a differential tariff. He believed the time had come when the consumers of this country, both those who eat the sugar and those who used it in producing some other product, would see that it was to their interest to promote the production of sugar within the Empire. Negotiations had recently taken place between the Government and the people interested in the aniline dye industry with the object of producing in this country the dyes which had mainly been obtained from Germany. The Government offered to lend so much money towards the establishment of the industry, but the manufacturers argued that they would eventually be exposed to the same dangers and troubles that the sugar-planters had experienced in the last forty years in the West Indies, namely, that the producers of the articles on the Continent having a highly-protected market in which they were absolutely secure were able to produce the article in large quantities and to ship the surplus to other countries. As the result of those negotiations the Government had now offered, he believed, a large loan for a period of twenty-five years at a low rate of interest, which was very much equivalent to the proposal the author had made, which he (Mr. Parker) supported. This war was equivalent to giving tariff assistance to the industry in this country for the purpose of preventing it from being drowned, suffocated and strangled by unfair foreign competition; and that was all that was required to produce a large development of the sugar industry in the British Dominions. Unless some security of market was guaranteed for a considerable number of years it was impossible to go to capitalists and ask them to invest probably twenty-five millions in erecting the factories, etc., necessary in the British Empire to produce the sugar required in this country. It seemed to him it would pay this country to adopt the principle suggested by himself and the author. It was no longer a question of helping a comparatively small industry, as it had been in the past, but of providing a cheap and steady supply of raw material not only in war time but in time of peace; and by increasing the area from which the supplies were drawn a more stable price would be maintained, which would not be liable to such great fluctuations as had occurred in the past. He was recently told that West Indians ought to have been contented with the fact that the Brussels Convention had abolished bounties. While that was perfectly true, it had not created free trade, because the British Empire could not send its sugar to foreign countries, while foreign countries could send their produce to England, charging what they liked for the article in their own country and sending the surplus here. It would be to the true interests of this country to offer such inducements to capitalists

that the most modern factories could be put up in the Colonies. An unfortunate impression had got abroad that there was antipathy and competition between British Colonial growers of cane sugar and home growers of beet sugar. That impression ought to be stamped out, if it existed. There was plenty of room for both, and the Colonies had no right to ask that this country should not develop its beet industry if it wished to do so. As a matter of fact, they welcomed the promotion of the beet industry in the interests of this country, and at the same time this country ought to welcome the production by its own Dominions overseas of such sugar as it could not produce itself. He hoped nothing more would be heard of any criticism of the Government for endeavouring to establish an industry which many people, himself included, believed would in the future be a very valuable additional agricultural industry in the country.

MR. W. T. CHADWIN (Secretary, British Sugar Beet Council) said the people of this country had had brought home to them through the war the reality of the dearness of sugar. The country depended for one of the necessities of life absolutely on outside sources. As this country was by far the largest consumer in Europe it ought to produce a certain amount of the sugar it required, but that it could produce the whole of it, as some people imagined, was quite a fallacy. It would never be able to produce two million tons of sugar a year without such a disturbance of other agricultural industries as would make it impossible of achievement. It was quite likely, however, that half a million tons could be produced in the country, and that would tend to check the wild speculations which took place when reports were circulated of the shortage of the crops of the world from various causes. The author had stated that an additional 700,000 acres within the Empire ought to be cultivated in order to meet this country's sugar requirements. Personally he had made a study of the beet-sugar industry, not only of this country but of the world, and he thought he was right in saying that, under normal conditions, at the present time the annual increase of the world's requirements in regard to sugar meant the produce of something like half a million additional acres every year to the preceding year's sugar crop. There was, therefore, no question of any competition between cane and beet, there being ample room for both. The one question that had to be discussed at the present moment was how this country was to secure such a position that the necessary capital could be found for establishing the industry. The sugar industry could not be started without a relatively very large capital. In some cases it was necessary to combine the growing of sugar beet and the manufacture of sugar, and that combination meant the employment of a larger amount of capital; but unless capitalists had some sort of security of a permanent nature it was hardly likely they would find the necessary money. It seemed to him that the means foreshadowed by the author met the case admirably. Personally he did not think it would be a hardship to the consuming population if a duty equivalent to ½*d.* per lb. were imposed on sugar. Sugar had been so ridiculously cheap that it had led to enormous waste taking place, and ½*d.* per lb. would permit of a good deal of elastic differentiation between this country, the Colonies and the rest of the sugar-producing part of the world, quite sufficient to protect the industry, both in this country and in the Colonies, and to allow of the necessary capital being put into the undertaking.

MR. J. J. EASTICK, F.C.S., M.S.C.I., said that the war seemed to have brought about the unity that was necessary amongst all the sections of the population who wished to produce sugar within the Empire. He had noticed of late there was a tendency on the part of those who had been advocating the policy of the growing of beet in England not to be selfish, but to reciprocate and offer the same protection that they desired to those who grew cane sugar. Those who had been long interested in the cane-sugar industry were also advocating that there should be a similar measure of protection to the home-grown beet as they had been asking for the Colonial-grown sugar. If the home and Colonial growers, and also the manufacturers who used sugar, could all be united, he had not the slightest doubt that the British community would gladly assist in granting a measure of protection from the unfair methods that had been adopted by Germany and Austria in building up their gigantic industry, which the English people had been foolish enough to allow the Germans and Austrians to do to the detriment of the Colonies. He was greatly in favour of producing the food required for the Empire within the Empire. He had now no axe to grind, as he was entirely out of the sugar trade, with which he was connected for thirty years; but he remembered writing in December, 1908, to the English Government telling them that he intended to start a sugar industry in England in which beetroot would be utilised. He received a reply to the effect that no duty was at present payable on beetroots grown for sugar in England, but that if works were started there was not the slightest doubt that an Excise duty would be levied. As under those circumstances he would have no defence against any action that Germany or Austria might take, he refused to build the works. Since then a works had been started, and although he was exceedingly glad to see that an experiment had been tried, he did not like to discuss that works because, to his mind, it was chiefly German and Dutch, and not English. He doubted whether it would be a success, not because sugar beet could not be grown in this country, for he was firmly convinced it could; but it was hardly possible to call an industry a British industry when a large number of old beet factories on the Continent, which represented more than three-

quarters of the capital that was required, was tacked on to a new industry. One good thing it had done was that it had introduced the thin end of the wedge, because the Government had felt they could not levy an Excise duty, although they had repeatedly said they would, so that this country could now defend itself against the unfair actions of its Continental enemies. It had been said that the Brussels Convention abolished State bounties. It was not the State bounties that were unfair—they were open and above board. There was another more insidious weapon than that, namely, the cartel system. Back in the early eighties he was sent to Magdeburg to investigate the question, and found they had an accumulated fund of five millions sterling to fight English and Colonial refiners. There was a surtax of £10 a ton on the Continent, so that the cartel could charge the home consumers whatever they liked up to that amount, and could utilise the fund thus accumulated to attack this country, and there was no doubt their object was absolutely to annihilate the British sugar industry. The surtax had been reduced to £2 10*s*., which could still be used to build up a fighting fund to fight this country. Unless some measure of defence was adopted, this country would still be at the mercy of Germany and Austria through the cartel system, which was far more important than the State bounties. The people of this country must not lose sight of the necessity of getting the surtax of £2 10*s*. abolished. The manufacturers in England were rather opposing any measure of defence or protective duty, but if the area from which sugar was produced was increased by giving encouragement to the Colonies to expand, that would have the effect of keeping prices down. Manufacturers were adopting a selfish policy in refusing that measure of defence which was necessary if the sugar industry of the Empire was to be increased, because capitalists would not embark their money in a concern unless some security was given to them. It must also be borne in mind that a large amount of sugar was being accumulated at the present time in Germany and Austria. The German Government had passed a Bill under which they had advanced money, on mortgage, on two million tons of sugar which had been stored, and which they hoped to dump on to the British markets after the war, and our Colonies would thereby suffer.

Sir Thomas Holdich said that, in a discussion which was not only commercial but technical and somewhat political, he could offer no useful suggestions, and he therefore merely asked the audience to join in passing a cordial vote of thanks to the author for his excellent and logical paper. It seemed to him that the author had entirely succeeded in proving his point. He desired to ask only one question in reference to the restoration of sugar cultivation in the West Indies. It would be remembered that the author had referred to the catch crops which were grown in the West Indies in lieu of sugar. Those catch crops appeared to him, when he was there not very long ago, to consist very largely of bananas, and on questioning the agriculturists there as to whether the banana crop or the sugar crop was the more productive and useful financially, they all plumped for the banana. He would therefore like to know whether the sugar cultivation in the West Indies could be reorganised so long as bananas proved to be so very productive and useful financially.

Mr. Byron Brenan, C.M.G., seconded the motion, which was carried unanimously.

Mr. E. R. Davson, after thanking the audience for the very kind manner in which his paper had been received, and for the vote of thanks that had been accorded to him, in replying to the point raised by Sir Thomas Holdich, said there were many districts in the West Indies where other crops than sugar had been grown, and there could be no doubt that the growing of bananas was one of the most paying industries of the Colony. He was afraid, however, there were other parts of the West Indies where sugar used to be grown, and where little was grown at the present time. One of the most depressing sights in the West Indies was to see acres of land lying fallow which used to produce sugar crops, and old sugar factories covered with creepers and tropical plants. That was a result primarily of the European bounty system. In conclusion, he desired, in the name of the audience, to thank both Lord Desborough and Sir Thomas Holdich for having presided over the meeting.

The Earl of Denbigh, C.V.O., writes:—I much regret that owing to my being quartered at present in Norfolk I only received yesterday your letter of January 27th, telling me of Mr. Davson's paper. So far, there has been much talk, and nothing but talk, and if only the Government would take a large view of the question, and either put up a good factory themselves or else declare, as a question of policy, that free German and Austrian sugar imports would not be permitted after the war—at all events, for a stated period of years—in order to attract capital and private enterprise, something might then be done. It is now purely a question of getting the support of that difficult and conservative person, the British farmer. Pay him such a price for a period of years as will make the growing of beet a really profitable thing, and you will get the raw material for several factories. The price which the factory can pay for beet is dependent on the price obtained for the finished article and on the cost of working. The latter is certain to decrease year by year as the industry, and especially the labour, becomes more and more organised and understood. In all probability after a few seasons the confidence of farmers will be more established, and they will realise, apart from the cash sales of roots, the benefit derived from beet cultivation as shown by improved succeeding crops.

They would probably therefore then be more willing to accept a lower cash price if sugar should again become cheap in the world. Against Government putting up factories there are many objections, for Governments do not often make a success of industrial concerns. Granting subsidies to factories is only another name for the much-abused system of bounties. Relax the strict principles of Free Trade for a term of years, as both such strict Free Trade purists as Lords Rosebery and Cromer are recommending in support of the dye industry, and the private capitalist comes in, and the industry goes ahead automatically. It is exasperating to see such an opportunity as the present slipping away.

TENTH ORDINARY MEETING.

Wednesday, February 17th, 1915; Sir Charles Waldstein, Litt.D., Ph.D., late Director of the Fitzwilliam Museum and Slade Professor of Fine Arts, Cambridge, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Horn, Wilbur F., M.A., Carlisle, Pennsylvania, U.S.A.

Mayeda, T., Shimboricho, Shiba, Tokyo, Japan.

Myers, Fred L., Kingston, Jamaica, British West Indies.

Salur, Raja of, Fort, Salur, Vizagapatam District, Madras, India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Buckland, James, 28, St. Thomas's-mansions, Westminster Bridge, S.E.

Khan, Choudhri Md. Aziz-ulla, Sahawar, Etawah, U.P., India.

The paper read was—

THE DECORATIVE TEXTILE INDUSTRIES AND THE DESIGNER'S RELATION THERETO.

By Arthur Wilcock.

It is now some twenty-five years since I received from this Society a prize for Decorative Textile Design. I was then a youngster relying entirely upon my individual effort, and the encouragement I received from so unexpected a recompense was all the more valued, coming, as it did, from a society so well qualified to pass a judgment.

The two designs that brought me this honour were those exhibited at the Arts and Crafts Society of 1889, both for printed cotton. It was at a time when my connection with trade and industry as a free lance was just beginning. One of these designs was produced, but I am sorry to say proved an utter failure. The producer assured me that, after all the expense he had incurred, the engraving of copper rollers, and the printing, he had not sold a yard of it. Why was this? Could I rail against the public for not buying a yard of what the Royal Society of Arts thought so worthy? No. Evidently the public had found something wrong with it. So I and my producer put our heads together to discover what had caused this pattern's ruthless rejection. After considering a full length of the printed cloth for some time, he said to me: "I know. Don't you see it?" I said, "See what?" "Why," he said, "the movement. It's all on the go, my boy." "Well," I said; "it was that waving effect I wanted to realise. I call it 'Waving corn and poppies,' you know." "Well," he said, "whatever you call it, or whatever the effect you wanted to get, it doesn't sell! So don't come here again with any more designs that are 'all on the go.' The public don't like 'goey' effects on their chairs and curtains." I went away crestfallen, for my artistic soul was in that waving corn! Since that time onwards I have learnt, and am still learning, many things the public don't like and do like.

I need not point you so obvious a moral which bears so directly on my subject.

My reason for attempting this paper is to place before you, as well as I am able, some facts concerning the decorative textile industries and the conditions of trade which govern their production, and especially to bring forward the limitations of the designer, upon whom these industries depend for novelty in design; to consider the advisability of aiming at a higher efficiency in the art worker, and to suggest what means, if any, can be adopted towards the more effective employment of the student.

Under decorative textiles I include woven silk damask, brocade, wool and cotton tapestry, damask linen, muslin, hand and machine printed cotton and linen, and wallpaper. The last-named can hardly be defined as a textile, in the ordinary acceptation of the term, although in its pattern and texture it is frequently an imitation of the woven textile. I include it, however, as one making a great demand upon the resources of the designer.

The various industries I have named, one would think, give ample scope for the employment of many skilled hands and much intelligent creative effort.

I have brought together a few of these decorative textiles which have been made for the furnishing and decorating trades as examples of recent production, not to ask your admiration nor to invite your criticism, but as representing designs which have received the approbation of that elusive phenomenon we call the public. In making a selection from the examples kindly placed at my disposal by various firms supplying these textiles, I have made a special point of selecting those which have had a more than usual commercial success.

It would be the merest platitude for me to tell you that the existence of an industry is maintained by the public, but I am afraid that our Art educationalists need to be constantly reminded of this vital truth in order to prevent their laudable enthusiasm for Art from obscuring the practical aim and end of production. However lofty our ideals may be, when translated into textiles they have to be sold at so much a yard if the artist and the various workers employed in that industry are to have the wherewithal to live.

Undoubtedly the best periods of textile design are those of the twelfth to the sixteenth century. The early Sicilo-Saracenic silks still appeal to the student of design for their beauty and simplicity, and I venture to think you would agree that the enormous creation of pattern from that time forward through the succeeding centuries, and through the various phases of fashion, would meet the needs of the most exacting taste of the present day. But since the character of a nation finds expression in its Art, we designers, instead of reproducing these bygone styles, must go on creating for the needs and taste of our own time--biased, it may be, in these days of commercial enterprise, by other motives than those that influenced the mediæval artist. Ours may be a more self-conscious Art, but it is an Art nevertheless that will leave its mark on the history of our time, whether for good or ill.

As in all periods, the best only is likely to survive for a later generation. I venture to say that among the best of our present-day productions many may be found of sufficient excellence to deserve a place in posterity, even though they may be created by the trade designer as distinguished from the designer with a mission, or, shall I say, who can afford to be independent of existing trade conditions. Such a one was William Morris. In him we had the producer as well as the designer—a fact too often lost sight of by those who complain of the dearth of originality in decorative art. And I make bold to say, that, giving the trade designer the same opportunity and means, we can to-day produce for the world many artists of the same ability.

Imagine, if you can, such a man as Morris, without any of his other great gifts, entirely dependent on the caprice of trade and without other means of livelihood, and you will appreciate that his fine work would have been entirely lost to the world. The designer is no exception to the law of opportunity.

Style in Design.

On this subject of style in design for textiles generally, we must assuredly be guided by our technical medium. Our sense of fitness must control us apart from other considerations. One can be gayer and more playful on one material, sober and more dignified on another. The gossamer texture of the muslin, for instance, calls for a lighter fancy than the treatment adopted for a heavy silk, which in its turn would demand a more stately ornamentation.

The wallpaper stands by itself as a decorative material, more dependent upon design than any other, because of its poor fabric. The textures of silks, velvet, tapestry and canvas are all in turn imitated on this material with a wonderful ingenuity and fidelity. It is of all decorative fabrics the most sophisticated. One cannot be guided here by the technical medium; in fact, the designer is required by the producer to forget the paper and aim at a treatment that will disguise its flat, uncompromising surface. At all events, such treatments are generally found to be the most successful in this trade.

In the printed cotton and linen the design is no integral part of the textile—that is to say, not woven. Delicacy and refinement in the design would naturally direct the judgment of the printer to a finely-woven cloth, whereas a broad and bold treatment of design calls for a coarser cloth.

Now, as regards the style of pattern mostly favoured by the public; those of you who have been acquainted with my work for cotton prints and wallpaper know that I have persisted in using a somewhat real rendering of natural flowers in my designs. I love natural flowers, and the public love natural flowers, and I suppose this is one of the reasons why I have been considered a "trade" designer. How much there is in this love of the æsthetic and how much of the business instinct, I will leave to your gentle tolerance. I must own, however,

to an interested affection for the necessities of life, and my first master of design must be blamed for this; for it was he who turned my young and guileless footsteps towards the sordid path of breadwinning. "A designer," he used to say, "who can do this natural style *well* will never be in need."

Since those days I have proved the wisdom of his statement, for, among other things, I have found few competitors in England contesting this most difficult of all styles. It is a style, moreover, that will accord with the decoration of most rooms of the average house. I, and my friend the public, welcome in the home the bright colours and the gay abandon of natural flowers not too far removed in their rendering to recall the beauty and the sweet perfumes of the garden.

Some who think I am violating an established canon of Art may agree with me that it is fortunate a restricted technical process of the printer compels all the convention necessary to make the design in every way acceptable as decoration for the fabric intended. In further defence, if any is needed, I am, as regards the cotton print, following on traditional lines established in England in late Stuart times, evolved from those first importations of Chinese porcelain and wallpapers in which you will find this natural rendering of flowers. This style has run through the Queen Anne and Georgian periods, variously influenced, until we arrive at the much-abused early Victorian period, when those very clever block-printed chintzes of Swainson and Dennys and Clarkson were produced. These are considered to this day by the better-class decorators of the highest decorative value, especially in the furnishing of the country house.

Technical.

It is not my intention, nor have I the time at my disposal, to demonstrate, even in a cursory manner, the various technical processes in each of the industries producing decorative textiles, but as an example of rapid production there is one in particular to which, in passing, I should like to refer you, viz., the machine-printed cotton.

In its manufacture (as in the manufacture of wallpapers) we have a huge cylinder machine, the large central drum (or bowl) revolving with the plain cloth against as many engraved copper rollers as there are colours in the design to be printed; these engraved rollers have each its own colour trough, in which revolves a felt roller feeding the printing roller with colour. The printing roller is immediately scraped clean by a sharp knife running the full length of the roller, thus leaving only the incised parts charged with colour (or thickened dyestuff and mordant). This impresses the plain cloth on the central drum with every atom of colour that remains in its most delicate incision. The printed cloth is then run into a steam chamber, which discharges the thickening matter, renders active the mordant, and fixes the dyestuff. It is then washed, and, after a finishing process, is ready for the market.

A twelve-roller machine can run off about three miles of printed cotton in two hours. It may be of interest to some to know that in this process, before the pattern has been consumed by the public to the extent of 10,000 yards, it has not brought sufficient return to the producer to compensate him for his outlay. So that when we speak of a design as commercially successful, it has had to be produced in enough quantity to drape, for example, all the windows on both sides of the Strand.

The printing-machine will cost somewhere about £2,000.

Now the hand block-printed cotton and linen are far less exacting as a paying concern in their demand for consumption, selling as they do at something like six to ten times the price of the machine-printed article, and the printing blocks rarely costing more than from £40 to £100, from which any length can be printed according to demand.

The characteristics of the block-print are its directness of method and its solid yet soft colour effects, not so mechanically even as the machine production and, like all handwork, it has a charm of its own unapproachable by any machine process.

The printed cotton has been in enormous demand of late, consequently the designer has received, year by year, much consideration from that industry. Any fabric in which pattern is so insistent on the attention must tire more quickly than one less insistent. The designs, therefore, for printed cotton and wallpaper have a shorter life, and are more in demand than, for instance, those for silk and linen damask, or any monotone effect. Indeed, the work of the designer would be almost gone should such be the only textiles used by the decorator.

Cheap production made possible by the large productive power of the machine, has only added to a more frequent demand for change.

In designing for the machine-printed cotton,

the designer has fewer technical limitations than for any other process. His most sensitive line can be produced by the engraver on copper with absolute fidelity, and if he takes full advantage of the process a twelve-roller machine will give him a palette sufficient for any colour effect desirable in purely decorative work.

In the case of the textile that receives its decoration from the warp and weft of the loom, the designer has greater limitations. Such effects as one is tempted to obtain in the print with a process so generous are quite impossible in a process with greater limitations.

Of all woven decorative textiles the silk brocade is the richest, and may become in the hands of a skilled designer a beautiful and rare contribution to industry. The lesser cotton decorative textiles are muslin and lace used for draping windows. The former is known in the trade as Madras muslin. It is of delightfully soft texture and of the simplest possible structure, consisting of a light ground net, on which is run a heavy cotton weft. That which decorates the fabric is caught down by the ground net, and that not so tied is cut away from the fabric in an after-process consisting of running over the surface with rapidly-revolving knives, similar to a lawn-mowing machine.

New processes are introduced from time to time in the textile industries, which it is necessary for the designer to understand; but the designer, working independently of the factory, is one on whom the industries rely rather for artistic than technical advice. The artist comes first, technicalities of a process come next, the designer not slavishly following, but rather leading to the limit of technical possibilities. He should be only sufficiently well acquainted with them as to be on nodding terms; not too familiar, lest they corrupt and degrade him. He is most effective as a designer when producing a maximum effect with a minimum of means. He must be able to think in those means. Just as fluent speech in a foreign language is impossible without thinking in it, so the artist's expression in the restricted language of industry will proclaim him eloquent or halting.

It is sometimes possible through this language to make the personality of the designer felt. Efforts have been made towards the better recognition of this personality of the individual designer and craftsman. The Arts and Crafts Exhibition Society is one of these. Its aims and ideals are excellent as affecting the hand-craftsman, and much good has doubtless been done by bringing him directly in touch with his public. But the public who appreciate the personal work of the designer and craftsman and who will buy the expensive handmade article is, I may remind you, an extremely limited one. The machine with its enormous productive power, its gigantic economic interests, and its complex and expensive distributing agencies, has not been sufficiently recognised. The machine industry supplies an immensely larger public, who are for the most part, if not wholly, indifferent to the personality of the artist and will listen to no language at all cryptic or symbolic.

To such a public we designers are asked to proclaim our artistic souls, to educate and elevate taste. Can one imagine a feebler medium of speech than is afforded by the textile? In some of those beautiful Persian silks of the twelfth and thirteenth centuries you will find Arabic inscriptions from the "Koran" very cleverly incorporated into the design. I wonder sometimes if the modern designer's educative mission would be served by some such *motif*. A text of Scripture or a little Ruskin? No. I think I know the public well enough to say it does not like to be talked at from its wallpaper or curtains. It rests content with something pleasing in colour and design. To trouble about the designer himself, however personal his manner, is as far removed from its thoughts as the maker of its butter.

The designer, therefore, is one who takes his place with the other impersonal units that go to make up a great organisation; any hope, therefore, of recognition by the public is out of the question.

Conditions of Trade.

Under the present conditions of trade the most the designer can expect is that he may be recognised by his fellow-designers and a few experts in the trade. He may also expect, as a foregone conclusion, that on the issue of any commercially successful textile by his producer, the competitors of that producer will ferret the designer out of his obscurity. This, then, is the only reward of successful expression.

If the artist's egoism is gratified by such recognition, he is well on the way to becoming a trade designer, especially if he has the means at command, and is willing to increase his output by attracting to himself other workers to assist him in supplying a larger demand.

A very elementary condition of trade connected with art industries producing pattern

design is the desire to capture trade by novelty. Indeed, the essence of all trade is the creation of demand, the making of things to-day that shall make yesterday's things seem old and out of date—the hazard of speculation on a prospective want. What wonder, then, that the man with ideals, failing to grasp this simple condition, has fallen out by the way and has become the malcontent or the revolutionary? What wonder that our Government design student, brought up and nurtured on the pure milk of classic art, finds he is not wanted? Moreover, the trades dependent on novelty in design do not want (for long) the man whose expression of art is restricted to one form, however good it may be. They want a man of the world, a man with his finger on the pulse of public taste, who will lend himself to trade enterprise, where, as an artist and man of discriminating judgment, he can seize on the salient features of any passing phase. By man of the world, I mean a man in touch with the world's movement, as my learned Chairman so well put it in his lecture here last year on "Fashion in Art and Art-Industry," when he said, in speaking of the designer: "He should not only know the past but he should be responsive to the expression of his age in every form, and the wants and needs and preferences of the society in which he lives, and for the tastes of which he is to cater. In one word, I maintain that the most efficient designer for our art industries, besides being a master of his immediate craft in design, should also be a man of the world, educated to perceive and understand the life about him in its most advanced, delicate and refined manifestations." Such a definition is, if he will allow me to say so, perfect in its completeness. But as a trade designer I would just like to add that to bring these qualities to a practical issue he must have the ability to impart his ideas to others, to those hands best suited by their peculiar ability to express them in the making of designs sufficiently varied to meet the demands of industries that call insistently for variety, not only of style but of interpretation, or shall I say "handwriting"?

My own experience leads me to believe that a great factor in the creation of fashion is the ability of the designer and producer, when once a demand is felt, to supply that demand and to press it home to the public in such quantity that it must in the end gain a fuller and wider attention. Here is trade risk. Quantity must be there, and if one considers what an enormous world enterprise trade is, both producer and designer must have large resources of production, or the demand will pass out of their hands into those more capable of dealing with it.

It will be readily understood that this production of quantity leads to over-supply. It also "gives one furiously to think" that the designer lives largely on that over-supply.

If, therefore, there is an over-supply of designers living on industries that are over-producing themselves, it will to some extent explain the present desperate struggle for life of the designer and the low morality in trade, which comes near to dishonesty, on the question of design copyright.

Mechanical science has enabled industry to give us a technically perfect product at a low price, but at what a cost, if uncontrolled by some better organisation of supply!

Again, another condition the designer has to contend against in trade is the modern tendency towards the limited liability company, which tends to eliminate the personal element. The departmental head—the buyer of designs—is not always, or, I might say, is rarely a man of great attainment—more rarely still is he endowed with sufficient knowledge of art to appreciate original effort on contrasting lines of style. He works on what he considers "safe" lines, which are always analogous. With a wonderful memory for patterns of his own and his competitors which have been commercially successful, he plunges more deeply into the mire of competition. We get, therefore, a greater sameness and an enormous over-production on one style. All are following, and very few have the courage to lead. Until, therefore, the selection of design reverts again to the more educated individual, not of less, but of more, business capacity, the call on the imagination of the designer will remain restricted.

It is common for the producer to blame the ignorance and incapacity of the merchant—the middleman between himself and the public—for lack of enterprise in taking up his industry's best and most original productions. The constant failure to convince the merchant of the merits of more original and better design has hindered and almost paralysed further effort. Especially is this so in the wallpaper industry, where, with rare exceptions, the producers have no facility for placing their best directly before the public.

It sometimes happens that the designer comes directly into contact with the textile

merchant operating apart from the factory, who depends directly on the designer, not only for artistic but also for technical ability. In these "dealers in specialities," as they are defined by the trade, no direct contact with the public is possible. The public voice reaches them through the retail buyer of the large and small shops, who has rarely any artistic conviction to influence his salesmen to "push" the most beautiful productions, but rather to push that which yields the largest profit. Of the various channels through which design has to travel in order to reach the public it will be interesting here to consider the influence of the salesman in direct contact with the public, and to this end, if you will allow me, I will read a letter from the director of one of our leading decorative textile emporia in London.

Relationship of Designer to Industries.

It may be gathered from the conditions which I have mentioned, especially taking into account the overproductive machine, that the relationship of the designer to the industries is a difficult one. How can it be otherwise when design is almost a superfluity, and there exists so little power in the producer to create an excellence or an originality which shall elevate it from a base competition ?

The industries depend upon the designer only just so far as excellence of artistic expression is needed. If all that is needed is a slavish adherence to past commercial successes or to copying museum specimens, then the office boy "with a taste for drawing" is almost all that is required. As things are, the designer novice will be always waiting, cap in hand, a dependent and mere "hack." It will take him many years before his relationship is anything like that of prophet and guide, which is the only relationship that makes the vocation worth while to the man of any ambition. The designer is without credentials or diploma, and seeks by the merit of his production a relation with industry which lasts only so long as that production remains in favour with the public. With a reputation for both technical and artistic efficiency, and having once gained the confidence of industry, his relationship becomes more and more intimate. No diploma or other standing is of the slightest value. Do not, however, be misled into the belief that the artist can be absent from the source of design supply. Industry is quick to discover and reject the mountebank or the charlatan. No mere exploiter of artistic labour can ever hope to establish a close relationship. Industry does not, as yet, buy its designs from the "Stores," and the design is, after all, so much professional advice put on the paper inseparable from the individual.

Design Supply to the Industries Considered Economically.

From my foregoing remarks I must have convinced you that the demand for design is almost fully met. No difficulty is experienced by the various industries in procuring such quantity and quality of design as is necessary for maintaining what they consider an effective output. As a result of careful inquiry in the wallpaper industry, with rare exceptions, I find this to be the case. The exceptions are those houses dependent upon a highly specialised production—perhaps leaders in one of the branches of this industry who are always in want of something rare, something of the highest merit on certain accepted lines. This want, they say, is never supplied; they will rarely risk anything on the encouragement of it, and the loss on an unsatisfactory effort on the part of the designer to produce this special result is invariably borne by the designer. We will, therefore, take this special demand for what it is worth; it does not alter the material fact that the supply of designs is such as to give no cause for concern to the industries, either as regards quantity or price. The dependence, therefore, of the designer on trade generally is infinitely greater than the reverse (which all tends to lessen his value and the value of his production). The average producer will unhesitatingly admit that design is too cheap; but he will ask you to consider the price at which he sells his textile, and the excessive competition he contends with. The designer may retort that by excellence of design, and its better recompense, he may lift the producer's textiles out of, and above, competition. But no, even a penny a yard for the designer will place the goods, says he, outside the market. The retail buyer has standardised the goods apart from any question of design. Such deplorably low valuation of design must surely be remedied. But accepting it, if we must, for the present, what can be done to meet it? Must designers meet trade on its own ground, and make it an economical industry, as is done in Paris? The decoration and dress textile trade have here raised up a special class of worker who meet it with something like the appearance of success. Without discussing the merits or demerits of the trade studio, the longer experience I have of pattern-design the

more am I convinced that design production, to be of any permanent value as a vocation, must, under the present conditions, be an industry in itself, and must consist in an economic organisation of variedly skilled workers.

And now that we are seriously considering the effective employment of the art students from our schools, would it not be wiser and more profitable for them to become part of such an organisation in closer touch with trade? It appears to be the only solution of a problem continually facing us. We in England could then compete more successfully with the Paris and German trade studios, and our industries need not be so dependent upon the foreign designer. I am sure at least of one thing: it would put a stop to the present enormous waste of serviceable workers who are now launched into the world as so-called designers.

It is doubtless owing to the many inefficient workers (the great part of them emanating from our Government and municipal schools) who go round the trade seeking the sale of immature efforts at design, that not only the value of design, but the trade's estimate of the value of designers as a paid class of workers, has been lowered.

May I here give you a recent instance that came to my notice?

One of our tapestry manufacturers in London, whose factory is in Belgium, and who has a large trade with the better-class decorative textile emporia, made me the proud boast that he obtained all the sketches he required at 20s. apiece, and, further, that he could buy tons of them at that price if he wished. But this is what I want you particularly to note. If these sketches were carried out further as practical designs, he would be willing to pay much more; but the men he employed did not possess the knowledge or inclination to do so.

Whether the raising of the standard of technical excellence in design submitted to the trade will raise the trade's estimate of the value of design and designers remains to be seen. I feel sure it will, as I am equally sure that, if in the last fifty years British industry had been served by a British school of design of greater efficiency, it would have compelled a higher value.

Now, as to the building up of such design industry as I have suggested, from what class of the community are we to draw our labour? Just that class that presents itself now, which both the Government and municipal bodies have been attempting to turn to profitable account, by scattering it broadcast into the camp of the rapacious trader.

Lewis F. Day, to whom designers owe so much for his lucid writings on ornament, and whose recent death is a great loss to us all, in an address to the members of the Design Club ("The Annual of Art Work," p. 27), said:—

The assumption that for a designer in any way to accommodate himself to economic or other conditions is to betray, or even degrade his art, is altogether unwarranted. I protest against it with all my might; and maintain that it is perfectly possible to be ready to meet the inevitable conditions to which design is nowadays subject, and yet to keep one's artistic soul alive.

Lifelong experience in design for trade and manufactures has not altered my conviction that a man may be ready to meet all the conditions to which design is subject.

I am fully aware that, in attempting to attack this economic problem, I am shocking the soul of the artist who is out to give of his best for Art's sake, but I am doubtful if there are any remaining who would not give much for the shelter of such an enterprise wherein he would receive a better reward for his labour. Think of the enormous waste of a gifted designer spending his time trying to find a market for his work. It is this side of the vocation that has driven many a good man out of it.

It would have been of considerable value, in dealing with this economic side, to ascertain (if it were possible) from the various British decorative textile industries the annual sum of money spent on designs with the outside designer here and abroad, and make some comparative statement, together with the wages paid to designers and art workers employed in the factories. It must amount to a very large figure; but the question then to consider is, How far this will go round, and whether the reward to the designer is not grossly inadequate, when it is frequently the prime factor in the value of the textile?

This much information, however, I have been able to gather from the British Wallpaper Combine, with its three millions capital. They purchase annually, in their various branches, 2,000 designs at an average price of £4 each, and out of this number 600 have been bought from the German designer, and fully 800 from Paris; thus, we will say, leaving 600 to be shared among British designers.

Also, as regards cotton-print designs, the C.P.A. purchase two-thirds of their designs in Paris.

In making any computation, however, it must

not be forgotten the British designer can and does sell designs abroad to the French, Belgian and German textile industries.

Copyright.

For a correct estimate of the economic value of design, we must not only take into consideration how the industry is protected by its own interests, but how it is protected by law. The law of copyright in design is still hopelessly inadequate to prevent colourable imitation, and the process of law is too expensive to facilitate speedy and effective action, while on the side of the designer the expense of any action must be borne by himself. The registration is inexpensive enough, consisting of the lodgment with the Patent Office of three photographs of the design with a fee, which in each section of the textile industry is: for wallpaper, *5s.*; for printed cotton, *2s. 6d.*; for tapestry, *2s. 6d.*

I need not remind you that a revision of the Law of Copyright and payment by royalty would put an entirely different complexion on the vocation of design, and would at the same time improve the position of the producer.

To sum up the economic aspect of design as applied to the textile industries, it would be misleading should you think that good design is not still required. The demand is there, but the over-production in the one and "selling" style leads to excessive and unfair competition in which the designer is made to suffer in an excessive ratio to the producer.

I now come to one of the most vital and important questions—

Education of the Designer.

Shall our Government and municipal bodies go on spending money on the education of the designer? Do the results of the past justify them in training more workers to fill an already over-supplied demand? We will admit, and I think they are now prepared to admit, that more practical lines should have been followed. The teacher of pattern-design has generally been entirely ignorant of trade requirements and technical processes. The young person who has been taken away from his trade for better Art education, that he might the better follow it after a course of study, has either found his way into the profession of teaching or has become a painter of pictures, or has, by misdirected effort, missed his way entirely. There has been a marked deficiency in the specialisation of the Art worker, and no connecting link with trade. Now, in this matter of pattern-design for the decorative textile industries, over 200 Art Schools throughout this country are at this moment still training students to become designers with a vague idea that pattern-design is of a value exceeding that of any other skilled work. All these young aspirants are going to be creative artists. What are we going to do with them? Let them take a two or three years' course and so lead them into a blind alley? No, the time has come when we must take this matter seriously. If industry still wants design, and is prepared to give it a decent wage, we shall have to concentrate and centralise any further effort, and bring to bear upon it, at the same time, a greater specialisation. Get into line or link up with trade and try to know its laudable aims. Educate the would-be designer to become an intelligent salesman, or anything to make him feel he is adding to industries, economy, and the advancement of Art. The showrooms, the warehouses, and the factories of England want men of equal intelligence with those of France and Germany, and they have not yet got them. It is the earnest and thorough workman that is wanted, not the dilletante artist who lives upon the chance of selling one design a month.

It is only through the efficient artist-workman, with much studio and trade experience, that we can arrive at anything like the designer with the qualifications that I have before mentioned. Let there be less confusion of mind than appears to exist in those responsible for the teaching of design in our schools. Once the student has shown a facility in pattern composition, it would be better to leave design entirely out of his curriculum and direct his whole attention to attain perfect draughtsmanship. Design will take care of itself. It is a very common attainment, even in the kindergarten, and it is valueless to Art industry with neither artistic excellence of rendering nor technical knowledge to accompany it. The employer of artistic labour, whether it be in the factory or trade studio, requires good workmen, good draughtsmen—not indifferent designers—workmen who know their immediate craft of drawing and painting, who will take infinite pains to render what to the average Art student would be the unconsidered details, yet to Art industry as a whole details are most essential and valuable.

The student must study the best historical examples of the particular industry he has elected to follow, and he must keep his mind open to receive any impression outside this. He must appreciate at their true worth, and on

their peculiar merits, all styles, whether Indian, Chinese, Jacobean, and all styles which are used n modern decorations. These may be so-called "decadent" styles, but are not to be ignored on that account, as more often they will claim greater powers of draughtsmanship. Take such a style, for instance, as Louis XV. Rococo. Without perfectly dexterous draughtsmanship it would become hopelessly debased and vulgar. Or take the Adam style. Without a perfect appreciation of its peculiar merit of chaste and beautiful proportion, it would become characterless and insipid.

In addressing the student for trade design on this matter of historical style, I would impress upon him the importance of cultivating its more perfect acquaintance. He must not fall into the temptation of thinking he is going to make a sensation in the world by the creation of a style all his own. It is not easy to be original on acceptable lines. Then I would ask him to consider in what originality consists—in what unexploited realms is he seeking originality? Let us suppose it is the realm of Nature, the source of all inspiration. He succeeds in cultivating a manner all his own—we will call it a personal style, unrooted in any past historical style. What is industry going to do with it?

Exploit it for two years, at most five, and then cast it out?

No! Let the student think less and talk less about originality, and give industry what it wants far more urgently—perfect workmanship. It is only through this that the perfect creative artist emerges. Lewis F. Day, speaking to designers, said: "I think it would be more decent of us if we did not claim to be artists, but just called ourselves workmen, leaving it to others to say if we were something more."

The Future.

Admitting that the Art workman for the textile industries has been unpractically trained and misdirected; admitting the want of education in the salesman and the factor; admitting that the economy of machine industry has reached a crisis and urgently calls for better government; admitting that the designer is under the heel of the trader by reason of over supply—what are we going to do?

Is it not possible in this country to find a means of giving some practical assistance to prevent its Art from becoming a negligible quantity, a sweated industry, and to help to elevate design to a place more worthy?

I can hope in the future—if the industries can combine to greater concentration on separate special lines of work; if the educational authorities will recognise the urgent necessity of some economic control; if better terms can be made between industry and the designer. Art has made a poor bargain with industry. No good Art was ever achieved without encouragement and support from either Church or State or individual. Take this away, leaving it to the tender mercies of commercial enterprise—the conditions of which I have given you—and it would be foolish to expect any other than now obtains. Indeed, I am surprised it is as good.

When one thinks of the advantages that have been ours since the industrial awakening of England at the great Exhibition of 1851 (which this Society of Arts inaugurated and carried to success), the enormous sums of money spent by the State on the education of the student of Industrial Art and on the priceless collection of objects in that palace of art, the Victoria and Albert Museum in London, and other museums, it is deplorable that so little has been accomplished. Our textile industries still buy the bulk of their designs in Paris. Germany has been supplying our great wallpaper Combine with more than one-third of its annual demand for designs. Our best and most efficient draughtsmen are imported from France, and our best engravers from Alsace and Germany, while our Government-trained student of pattern-design is either unemployed or has drifted into other work. It is idle to say this is the fault of trade for not wanting Art. It is the fault of those advisers on matters of Industrial Art training who have set themselves to the quixotic task of tilting at the windmill of commerce, so that Art has been thrown naked and undefended into the cruel arena of a trade governed only by a profit-making standard.

In conclusion, it is gratifying to find among these industries of which I have been speaking some producers who are still conscious of the true value of the artist—men of good taste and artistic sympathies. They recognise that Art cannot flourish in anything but a generous atmosphere, and these men, we feel sure, will become leaders in their trade. They recognise also that the public upon whom they depend, whatever their choice of style, will, with rare exceptions, always choose the *very best* of that style. We designers, therefore, cannot do more than strive for this best, and never rest content in taking a place inferior to that of the foreign competitor.

We can, I fear, never look upon the profession of design as anything approaching in importance that of the architect or painter. It is, and always will be, a small profession, whatever importance it may have in the eyes of the State as influencing its industries for good and helping towards a higher appreciation for design. It will remain by reason of its limitations one of the lesser Arts. Certainly in its relation to the decorative textile industries it will never attain to a position of command, but must rest content with that position of servant and guide.

[Mr. Wilcock desires to take this opportunity of thanking the following firms who kindly lent specimens of textiles to illustrate his paper:—Messrs. Maple & Co., Ltd., Tottenham Court Road, W.; Messrs. James Shoolbred & Co., Tottenham Court Road, W.; Messrs. Harrod's, Ltd., Brompton Road, S.W.; Messrs. Story & Co., Kensington High Street, W.; Messrs. Warner & Sons, Newgate Street, E.C.; Messrs. B. Burnet & Co., Ltd., Garrick Street, W.C., and Messrs. Stonards, Ltd., Paternoster Buildings, E.C.]

DISCUSSION.

The Chairman (Sir Charles Waldstein, Litt.D., Ph.D.), in opening the discussion, said it was always a great privilege to listen to a man who had not only considered the theoretical or literary side of his work, but who was himself a producer, and at the same time had pondered much over the broader aspects and the essential philosophic questions of his vocation in life. Such a man was the author. But he (the speaker) had to confess that, with all the numerous suggestions the author had made, and which set one thinking in so many directions, he was confused. He had taken up many of the suggestions and tried to follow them out. They had led him in one direction, and then the author at once had sympathetically drawn him in another, and he did not know, as Chairman, at the end how to summarise them all, or how profit was to be gained most directly by the author's vast experience and eloquence. For instance, the author had enjoined upon the artist who had devoted himself to art industry, and the tradesman who was inspired by artistic ambitions, the fact that they could not command, but were only servants and guides. The author was much too humble, and he had been at times too kind to the public, and, still more, too kind to the intermediaries who stood between the public and the artist. He (the speaker) did not agree that there was an essential difference between the artist and the designer—the art worker. From one point of view, every artist, however lofty his ideals of his art, worked for a public. He did not stand in rapt admiration in his study—be he sculptor, or painter, or musician—and gloat upon the beauty of his own realisation of Art with nobody else to see it. And, meanwhile, how was he to live unless those who did see it and admired it would pay for it and help him to live? He (the speaker) quite admitted that the designer could not appeal so directly to the public as the painter, sculptor, or musician could do. Very often he was worse off, and could not get a public at all, but he had ultimately to go to the public. The thing the designer had to complain of was the tyranny of the trade, and the tyranny, to a greater extent, of the middleman, who stood between the public that admired, and that could be made to admire, and the production of the work which really and honestly did appeal to them. The middleman did not consider those points, but was led away by other considerations which had nothing whatever to do with the intrinsic artistic quality of industrial art itself. One of the most admirable suggestions was that such middlemen should be educated and be brought more directly in touch with the artistic side of the designer. No good salesman or manufacturer should be devoid of education on the artistic side and on the industrial side of the goods in which he was dealing. That was one of the great problems of modern industry all through. A man who dealt in textile fabrics or decorative work should know all about their manufacture and be a man of taste himself. But how could this educative work be carried out? He had expected to have heard some more definite suggestions put forward by the author. Allusion had been made to the Arts and Crafts Exhibitions. They were good, but they were limited almost exclusively to hand-made work. Nobody valued more highly than himself the beauty of real handicraft work, but were we to turn our backs on machine work? Was it not possible to have exhibitions in which, side by side with the handicrafts, were also machine-made goods? And could not something be done to abolish the stupid antagonism between art and craft? Every true artist was an artisan. In conclusion, he would ask the public not to be too hard on the State-aided institutions. They had done much good. If it had not been for them, where would be the interest in Art throughout the whole country? Where would the young men be who, after all, were learning to draw there? and what was the trade going to do if people did not know how to draw? Were those young men going to be prematurely taught from the practical point of view on childishly made instruments which were to represent the processes of manufacture, before they even knew how to draw, before they had an artistic taste or education, which the schools must give them? Many suggestions were being made as to how to reform the Art Schools. How could such be carried out? Once give the schools the means of educating the public, and once give them a more immediate touch between the designer and the public, and the tyranny of the fashions and the tyranny of the trade might possibly be overcome.

Dr. William Garnett (Educational Adviser to the L.C.C.) said that he knew little about Art or design, nor was he an economist, and he supposed that it was in consequence of his interest in educational work that he was called upon that evening to say something in defence of the Art Schools. The author stated that artists cultivated Art and forgot the public. It seemed to him (the speaker) that the tendency of all academic schools must be to work independently of public demand; and they were not to be entirely blamed for that. Once the questions were introduced, Did it pay? Would the public take to it? all the highest work of our Universities and our Schools of Art would be destroyed. The great discoveries upon which practical inventions had ultimately depended had been made by men who had worked at science for the sake of science, and not for the utilitarian results which might have been expected. He quoted in that connection the history of the dynamo and wireless telegraphy. But that was not all that was required. Men were wanted who would put one hand on industry and the other hand on science or art, as the case might be, and act, as it were, as the mediator or interpreter between the two, and then the great discoveries of the scientist would be made available to the practical man for the development of industry. Such a man was Lord Kelvin. Kelvin's success in one branch of his work was due to the fact that he was a practical yachtsman as well as a great electrician, and he combined his experience of navigation and of the wants of navigators with his knowledge of electricity and magnetics and mechanics, and so produced methods of satisfying those wants. The author said that the designer required to have a nodding acquaintance with technicalities, and not a familiar acquaintance, lest they degraded him. He (the speaker) was ready to join issue with the author on that point. The nodding acquaintance of the science man with technicalities was good; but a more intimate acquaintance was better, provided that he confined himself to his science—that he was not a worse scientific man because he was the greater technical expert. He (the speaker) pointed out that it was through the association of the technical expert, James Watt, and the Professor of Physics in the University of Glasgow that the steam-engine had come to be a practical working agent in all our factories. All he (the speaker) had said about science he thought applied equally to art. Schools of Art properly developed Art for Art's sake; but the industrial Art School (which was, or might be, a thing a little different from Schools of Art) must take the very best of the work of the Schools of Art and must adapt it to the requirements of industry. That was where, perhaps, our educational institutions fell short. The public was master of the situation, and the public could only be led by the expert very gently indeed. First of all, the public wanted machine-made goods because it could not afford to buy purely hand-made goods. Therefore, if Art was to penetrate into the dwellings of the middle classes and the poor it must be through machine-made goods, and art teachers must get that sympathy and that touch with machine-made productions which would enable their pupils to adapt their designs to the requirements of factory industry. There artistic design differed to some extent from scientific invention, since novelty and not utility was the test of success very often in Art work. So the superintendent of the school of industrial Art, while he kept one hand upon artistic development had to keep the other hand very carefully upon the pulse of the public. The weak point in English Art Schools very often consisted in what the author had called unconsidered details. Details, however, were essential to make a design practical. If English Art students who had the genius for inventing a new design would take the trouble to produce it as a German artist would, in such a way that it could immediately be put upon the rolls, or otherwise interpreted into the requirements of the machine, then they might expect to get paid, not only for their ideas, but for their work. As it was, the manufacturer had, in addition to paying the designer for his idea, to pay somebody else to interpret it so as to make it pay.

Mr. John Sanderson said he had always noticed that papers on artistic work contained a note of pessimism; but as far as his own trade, that of the manufacture of wallpaper, was concerned he would like to say that in England the artist, backed by the manufacturer and aided by the suggestions from the decorator, held the premier position in the world. Continental people, who were a little out of the common and desired something really nice, always used English wallpapers, and the same thing applied to the United States. The German producer of designs was to his (the speaker's) mind exactly like the German producer of everything else—he was mainly inspired by the Englishman, and then, with infinite care and pains, produced and reproduced things very much like what Englishmen had produced, sometimes putting rather a practical note into them. He thought the trade suffered very much from the terrible mixture which it had in it of fashion and Art. Other trades were not hampered in that way. With regard to the salesman, he was a man very often shot at and abused, whereas generally he could not help himself. He remembered that, when he first began, an old and practised salesman said to him, "Never mind what you like, or what you think the customer ought to have. Ladies as a rule are the choosers of wallpapers, and it is a most unpleasant business to attend to them. They flutter from one flower to another like butterflies. You watch them flutter, and the moment they show any signs of alighting on one flower, nail them to it!" That was very practical advice, and he had found it answer very well. Coming to the main point of the paper, he was

puzzled to know what to say. The result of the teaching of the students was no doubt unsatisfactory. He was constantly getting letters from philanthropic ladies and others who took interest in boys, saying that the boy's Art master considered him a genius, and sending up drawings which the boy had made. Well, the drawings were very good and as correct as they could be; they conformed to all the rules of design, but they would not sell. He thought that if many of those lads, after learning to draw, were sent into a warehouse to earn their living, at the same time getting an outlook on the world and on their own particular industry, and attended Art classes with the discrimination of a man instead of the easy appetite of a youth, it would not only give them a better education, but would sift out those who had not enough genius to become real designers, but who would probably become good salesmen and workmen, or who even might go into the handicrafts. Perhaps something of that sort could be managed, but it would be for the artists themselves to do it; the manufacturer, or the middleman, or the salesman, or the public would not be able to assist very much in that respect.

Sir Cecil Harcourt Smith (Director and Secretary of the Victoria and Albert Museum) said there was not much he could say, being a public official; but the author had mentioned the Victoria and Albert Museum, and he should like to state how extremely anxious all those who were connected with the Museum were to identify themselves, as far as possible, with the interests of industrial Art of to-day, and not only with that of the past. He very much hoped that when matters became more settled it would be possible, with some space which would be reserved, to arrange for an annual exhibition, or perhaps even more than one, showing what the industrial Art of to-day was, pending the institution of some building which would deal with the matter much more thoroughly. He thought it was a very essential thing for the interests of industrial Art of to-day that there should be some institution which made it a point of showing to the public at large and to manufacturers and to salesmen what was being done generally throughout the industrial trades; and, more than that, that there should be some place where experiences could be exchanged, where people could meet and discuss points which really interested one and all.

Mr. W. Foxton said it had occurred to him whilst listening to the paper that the author was advocating a sort of trades union for designers. He (the speaker) could not agree with him on that point. Mr. Wilcock was a very good example of the survival of the fittest, and if he could bring about what he desired in the way of a trades union for designers, he (the speaker) thought it was very possible it would foster a lot of mediocre members, and that the good results which were being obtained to-day would not continue.

The Author, in reply, said the discussion had not been quite as practical as he wanted it to be. He had not submitted any suggestions; in fact, he had purposely refrained from doing so. He thought certainly that the suggestion of Sir Cecil Smith was an excellent one. They all looked to the Government. There was not the slightest doubt that if only the Government could put its mark upon the good men it would immensely raise the status of the designer, but they must be the fittest of the lot. He did hope that the schools would take warning not to bring too many men into the market, because the result would be disastrous. It would be a very proud thing for him to say he had done something to link together commerce and Art. He was doing what he could. He felt the schools had been keeping far too aloof from the trader. They had never troubled to understand the trader's needs or requirements. If sympathy could be brought about between the one and the other they would come together in the very near future.

Mr. Alan S. Cole, C.B., writes:—I am sorry to be prevented from attending the meeting when Mr. Arthur Wilcock is to read his paper on "The Decorative Textile Industries and the Designer's Relation thereto." Having had the privilege of seeing a proof of the paper, I have jotted down a few remarks which I should have offered in the course of the discussion following the reading of the paper.

The subject of decorative textiles is one that has interested me for many years, particularly the apparent evolution of processes to produce such textiles, as well as that of their schemes and styles of ornament. Mr. Wilcock, with the advantage of long successful practice and wide, fruitful experience, in close touch with the modern trade and methods, has dealt with phases of them.

It is on the strength, or weakness, of my past official connection with the now defunct Science and Art Department and the South Kensington Art Museum that I propose to question the validity of one at least of the opinions at which Mr. Wilcock has arrived, namely, that "it is deplorable that so little has been accomplished" in view of the advantages the country has obtained since the great Exhibition of 1851. I readily admit that his contention is applicable to results obtained during the present century; but I venture to think he has not considered adequately the condition of things as it was in 1851 and the results of work for the remaining years of the last century.

The Department of Science and Art and the South Kensington—the Victoria and Albert—Museum were the immediate outcome of the 1851 Exhibition, and were means by which it was hoped to stimulate the education of producers and consumers of Art manufactures and of Art productions generally. The fostering of these means was regarded suspiciously at first by Parliament, who reluctantly made grants of money to aid it,

In the then controlling official administrative circles the possible value of a system to encourage public intelligence in Art manufactures does not seem to have been appreciated. A few members of both Houses of Parliament were able to spur on officialdom; and a general system grew which included the careful development of the functions of the Science and Art Department, and the National Art Training School at South Kensington, with the Art Museum. A specific object was kept in view and was aimed at for achievement through this system.

The basis of the general system as it affected institutions in the country, apart from those at South Kensington, was co-operation between local efforts and the assistance given by Parliament. At starting, this co-operation put life into some dozen moribund Schools of Art (or design, as they had been rather erroneously called), and called into existence many more Schools of Art. The management of them was local, and for local purposes. The conditions for distributing Parliamentary grants were comparatively simple and encouraging. But as time went on, although Parliament became more generous, official conditions for distributing the Parliamentary grants became more complex and restrictive. Local management seemed to lose much of its vigour in making the local schools beneficial for local purposes. Still, it is well on record, at least of the last quarter of the nineteenth century, that educational and industrial authorities in France, Germany, Russia, and other European countries, recognised our Schools of Art, our South Kensington Training School and Art Museum, and our artistic manufactures with admiration. Indeed, our Art manufactures stood very high in the foreigner's estimation, especially that of France. Parliament continued to increase its grants; but officialdom increased its shackles on local action, and thus within the last twenty years officialdom has, I think, become mainly responsible for the spread of an opinion that our machinery to improve Art manufactures has not latterly secured proper results. But I think that Mr. Wilcock goes too far in deploring what has been done in the course of sixty years or so. Mr. Wilcock talks of "our Government-trained students of pattern designs"; and such, no doubt, they have gradually become. It seems, however, that were the existing forms of official control in distributing the Parliamentary grants to be very greatly relaxed, Schools of Art would obtain greater freedom of action in training students for the benefit of local needs, and misapprehensions about "Government-trained" students would be diminished, and this with advantage to all concerned. In fact, a return to the original and definite policy upon which the whole system was launched is much to be desired. I know that in high quarters an opinion has been expressed that Teutonic methods of education are good examples for this country. But we are now learning otherwise. However much we may grumble in a healthy way at our Art institutions and schools and their influences, do not let us forget that British local efforts, aided by Parliamentary grants, have provided us with a better network of fine technical, scientific and artistic institutions than any other country possesses. It is possible that we have not of late years made the best use of them, but that, I think, is due to causes such as I have referred to.

Mr. Wilcock alluded to the industrial Art works of our time, and that among the best of them many may be found of sufficient excellence "to have a place in posterity." He may have overlooked the fact that the Board of Education is the guardian of a certain number of such works, and not British works only. They do not, however, find proper places in the collections of the Victoria and Albert Museum. I think, therefore, that the Art collections at South Kensington might very usefully be reorganised and displayed, with the distinct aim of encouraging, amongst producers and consumers, knowledge of the world's history, brought up to date, of Art manufactures and decorative work. The Museum's original purpose was to be an adjunct—an encyclopædia, as it were —to the National Art Training School or Royal College of Art, and also to serve the local Schools of Art. At present, in the vast premises of the Victoria and Albert Museum, Art collections are becoming perplexing through redundancy of similar examples; and at the rate at which gifts and bequests of almost any works of art are accepted, and made much of, the redundancy and perplexity are increasing. Enormous ranges of wall and floor space are covered with types and examples duplicating and triplicating themselves, over-illustrating the same methods of production and styles of design and work. The clear and original educational function of the Museum is quickly becoming befogged. Through the influence of such papers as Mr. Wilcock's, and discussions of them under the auspices of the Royal Society of Arts, a powerful lever can be brought into action for the release from official thraldom of the country's efforts to do steady work to benefit Art industries.

Sir Cecil Harcourt Smith writes:—First of all, I should like to express the pleasure it gives me to listen to the views of a practical designer as well known as Mr. Wilcock on such a subject as that of design. This question is, of course, one that most intimately concerns the Victoria and Albert Museum and the Board of Education generally, and it is of great importance that we should know what is the view taken by him and his colleagues of Government efforts in this direction. One of the chief difficulties which, I suppose, confronts all of us, is that of co-ordinating theoretical instruction in design with the practice of it. Personally, I have always felt that one of the biggest factors composing this difficulty is the machine, which, as he says, has never been yet sufficiently recognised in its relation to theoretical instruction in design.

I must confess to being somewhat depressed by the view that in the ordinary economy of things the designer, even of a successful product, must be content to resign any hope of recognition by the public. I cannot really think that the case is as bad as that. If it is so now, it must be surely because the conditions of artistic trades are not yet properly adjusted to new circumstances, and a time must come when the best work will always achieve a position above the mere impersonal.

As I understand it, we are confronted with two opposed propositions, roughly as follows: on the one hand we have a quantity of cheap goods which command a ready sale, but which are for the most part of bad design; on the other, we have a plethora of good designs for which there is no market. One of our chief difficulties seems to lie in the co-ordination of these two facts, which is, after all, to some extent, a question of education, and which involves the establishment of the truth that what is cheap need not necessarily be nasty.

EMPIRE NOTES.

Australian and New Zealand Exhibits at the Panama Exposition.—Notwithstanding the war and the part which Australia and New Zealand are taking in it, both these countries, with a view to extending their trade relations with the United States, have determined to avail themselves of the opportunity afforded by the opening of the Panama Pacific Exposition, and are therefore sending large and carefully-selected cases of exhibits to San Francisco. These will be placed in the special buildings which have been erected for them. The Australian building, which is finished in native hardwoods and fitted with show-cases and furniture made from Australian timbers, will contain exhibits of wooden articles, products of the pastoral industry, including over 600 fleeces, minerals—among which is a collection of opals valued at over £7,000—corals and shells, agricultural products, tanning materials, furs made from the native bears, kangaroos and sea animals, rubber and cotton, fish and birds, glassware, native weapons and specimens of native work. In connection with the building is a park and aviary, in which will be shown a number of animals and birds in appropriate surroundings. There are two cold-storage rooms for meats, fresh fruits and dairy products. The New Zealand exhibits will consist of frozen meats, fresh vegetables, cheese and butter, fibre, hemp and flax, grains and native grasses, wool and woollen goods, and minerals. These will be displayed in the Palace of Agriculture, in which the New Zealand Government has taken over 14,000 square feet of space. In the New Zealand building, specimens of Maori art and weapons, trophies of the chase, and kauri wood and gum will be shown, while in a large conservatory there will be specimens of the native flora. Both the Australian and New Zealand buildings are equipped with moving-picture theatres, in which films illustrating the scenery, life and industries of the countries will be shown. Altogether the exhibits promise to be an impressive demonstration of the resources of Australia and New Zealand, and will doubtless prove of service, in the interests of settlement and trade, to both countries.

Rhodes Scholars from Greater Britain.—According to the statement for 1913–14 of the trustees of the Rhodes Scholarship Fund, the number of scholars in residence at Oxford was 177, of whom 76 were from the British Empire oversea. Since the beginning of the war, a large number of the British students have taken commissions or enlisted as privates in the Imperial Army or in the contingents of the various Dominions. These will resume their scholarships at the end of the war. Twenty of the 88 United States scholars, included in the above total, have been given leave to assist in the work of distributing supplies under the auspices of the International Commission for Relief in Belgium. The following list gives the lines of work taken up by the 504 Rhodes scholars who have completed their terms:—Education, 167; law, 130; clerical work, 20; social and philanthropic work, 8; medicine, 31; scientific work (research), 8; engineering, 4; mining, 4; diplomatic and consular service, 6; Civil Service—(British Empire) 22, (U.S.A.) 3, (Germany) 33; Army—(U.S.A.) 1, (Germany) 1; journalism, 13; business, 22; farming, 12; miscellaneous, 4; unsettled to date, 11; and unknown, 4.

The Decline in Emigration.—Before the beginning of the war there had set in a considerable decline in emigration, arising from the better trade conditions in the United Kingdom and from the less favourable conditions, allied with the slackening of efforts on the part of the various Governments' advertising agencies and propaganda, in the oversea Dominions. The incidence of the war, however, put a final stop upon the outward movement, as the Board of Trade statistics show. In 1913 the number of emigrants was 389,394. In 1914 it was 214,138. The arrivals, on the other hand, numbered 85,709 in 1913 and 104,995 in 1914. The net emigration figures, therefore, which for 1913 were 303,685, for 1914 were 109,143, showing a falling-off of no less than 194,542. The emigration to Canada fell from 190,854 in 1913 to 78,305 last year; to Australia, from 56,779 to 32,388; to New Zealand, from 14,256 to 7,871; to South Africa, from 10,916 to 7,785; to India and Ceylon, from 6,810 to 6,751; and to other Colonies from 5,432 to 4,996. The totals for the British Empire were 285,046 and 138,096 respectively. Emigration to the United States

also fell from 94,691 to 69,705, and to other foreign countries, from 9,657 to 6,337. It is interesting to compare with these figures those for arrivals during the two years. Those from Canada, which were 26,288 in 1913, rose to 34,050 in 1914; from Australia, 12,351 and 13,510; from New Zealand, 2,446 and 2,869; from South Africa, 10,541 and 11,267; from India and Ceylon, 5,928 and 7,958; and from other Colonies, 3,971 and 4,977 respectively. The totals from the British Empire oversea were, for 1913, 61,525, and for 1914, 74,631. From the United States the arrivals in 1913 were 16,619, and in 1914, 20,890, and from other foreign countries, 7,565 and 9,474. It will be seen that in all cases the arrivals for 1914 exceeded those for 1913, and that in the case of South Africa, India and foreign countries, with the exception of the United States, the numbers arriving in the United Kingdom exceeded the departures. There is no doubt that, at the conclusion of the war, these figures will be reversed, and, so far as the British Dominions oversea are concerned, necessarily so, if those Dominions are to be peopled with British settlers and to continue to grow into strong British communities.

Snow as a Canadian Asset.—The *Brockville Times* of Ontario, referring to a recent snowfall in Canada, describes it as "a blessing to the country and a commercial and sanitary asset, which should be valued as such." Dealing with the latter point, the paper says that the fall was "hailed with delight by everyone, not only because it created good seasonable winter conditions and encouraged business, but because it cleared the air and laid the dust which was filling the houses and stores and the lungs with germs." This view was confirmed by the *Toronto Globe*, which says: "Some day, Canada will be proud of the title 'Our Lady of the Snows,' which Kipling conferred upon the Dominion." Evidently the people of Canada are beginning to realise, in view of the reduction in the snowfall which has been experienced in the last few seasons, that snow has its value, both as a fertiliser and an atmospheric cleanser. At one time, however, it was thought necessary to repress, as far as possible, any reference to the hard winters with which Canada was usually visited, for fear that intending settlers might be frightened away from so inhospitable a country. But now that the diversity of climate which Canada possesses is becoming more fully recognised, and the fact is better known that her winters, though in some parts severe, are dry and bracing, accompanied for long periods with bright sunshine and affording facilities for easy transport, social gatherings and exhilarating winter sports, the belief is growing that, instead of being a drawback to the people of moister countries, the winters of Canada may prove an attraction. This feeling among Canadians is certainly likely to be fostered, after the experiences of the Canadian Contingent on Salisbury Plain, where rain and mud have given the soldiers of the Dominion a much higher opinion of the winter seasons in Canada than even they had before, and a conviction that snow, under a Canadian sun, is far preferable to the slush of an English winter, under a leaden sky.

The Coal Measures of Queensland.—The Queensland Geological Survey publishes some useful particulars as to the coal measures of that country, by Mr. B. Dunstan, in which, while dealing specially with individual coal areas, some general facts are given. Of a total area of 73,000 square miles, representing the geologically surveyed measures, the recognised coalfields cover 20,000 square miles. Most of the present supply comes from the Trias-Tura measures, mainly confined to the south-east of the State, covering an area of 83,000 square miles, which includes an area of 2,000 square miles of coalfields, proved to contain coal seams, whether workable or not. The permo-carboniferous formations, covering 30,000 square miles, include 16,000 square miles of coalfields. These lie further inland, and are still largely untouched, but with the development of communications will be an important source of supply. The cretaceous measures (20,000 square miles, with 2,000 of coalfields) are of less importance, the quality of the coal being inferior. The writer endeavours tentatively to estimate for each coal area the actual probable and possible coal reserves in existence, limiting the calculation to seams not less than a foot thick, and not more than 1,000 ft. below the surface. The general result is to show that the basin of the Dawson-Mackenzie Rivers contains far more probable resources than all the other parts of the State put together. The mammoth seam in the Mackenzie River area has a thickness of 20 ft., and the probable reserves, estimated on the assumption that one square mile round a spot is the limit of probable occurrence, are put down as 450,000,000 tons. The Clermont area, with a seam of 66 ft., but of less extent than the Mackenzie area, affords a probable reserve of 300,000,000 tons. Queensland's yield of coal in 1910 was about 870,000 tons, or 11·37 per cent. of the whole of Australia. The output has been gradually increasing, from 323,068 tons in 1895 to 891,508 tons in 1911, the total to the end of that year being estimated at 13,251,883 tons. Although gold-mining is an important industry in Queensland and in other Australian States, it is evident that coal will exceed it in importance, as the industries of Australia, which are only in their infancy, become more fully developed.

The Murray River Storage Scheme.—An important step towards carrying into effect the proposal for locking the Murray River in

Australia has just been taken by the introduction of a Bill in the Victorian Parliament, to enable that State to carry out its share of the agreement made between the Commonwealth and the States of New South Wales, Victoria and South Australia. The proposed work, it is estimated, will cost £4,440,000, towards which the Commonwealth and South Australia are each to provide £1,000,000, and New South Wales and Victoria £1,220,000 each. The works will comprise:—(1) The provision of storage at Cumberoons, or some other suitable site in the Upper Murray; (2) a system of storage at Lake Victoria; (3) weirs and locks on the Murray, from its mouth to Echuca; and (4) weirs and locks on the Murrumbidgee, from its junction with the Murray to Hay, or, alternatively, at the discretion of the New South Wales Government, weirs and locks on the Darling from its junction with the Murray. The works on the Murray above its junction with the Darling are to be constructed by New South Wales or Victoria, jointly or severally. The provisions relating to the supply of water to South Australia may be varied in drought times, and the minimum quantity to be allowed to pass shall be sufficient to fill Lake Victoria storage, and with it maintain a monthly supply at the outlet of the lake of 134,000 acre-feet from November to the end of January; 114,000 acre-feet during March, September, and October; 94,000 feet during April, May and August, and 47,000 feet during June and July. Such provisions are not, however, to take effect until the Victoria and Murray storage works are effective, or the expiration of seven years from the time when the Act comes into force. The full importance and advantage of this great undertaking can only be realised in a season of drought such as that through which Australia has been recently passing, but, in the general interests of irrigation, in each of the States directly affected the completion of the work will be an invaluable boon to the Riverina and other settlers in New South Wales, Victoria and South Australia.

GENERAL NOTES.

Comité Belge pour le Commerce avec les Alliés.—Steps have been taken to organise an office called for "Commerce with the Allied Nations." The aim is twofold: to secure for well-recommended and fully-qualified Belgians the agency in Belgium of British firms, and to answer inquiries from Belgian firms who are desirous of replacing foreign goods by their English equivalents. Trade papers, catalogues, etc., will be filed in order to give all possible assistance to inquirers. The temporary address of the office is care of The London Chamber of Commerce, 97, Cannon Street, London, E.C.

The Telephone System in Italy.—Under an act of the Italian Parliament of July 15th, 1907, the telephone service in the larger cities of the kingdom was taken over by the Government through the purchase of the plants of the two largest operating companies. Several smaller companies were allowed to continue operations for ten years before being taken over by the Government, and in 1913 the term was extended in some instances for ten years longer. The Government operates the principal long distance lines, and has exchanges in sixty-nine cities. On June 30th, 1911, the latest date for which the statistics are available, the number of Government subscribers was 51,828, and of subscribers to private lines 24,233. The number of Government subscribers in the principal cities was as follows: Milan, 11,207; Rome, 10,025; Genoa, 5,783; Turin, 5,050; Naples, 3,671; Florence, 3,347; Venice, 2,045; Bologna, 1,628; Palermo, 1,293. There are ten principal concessionaire companies. The exchange equipment of the Milan central office is of two kinds—the common battery multiple switchboard of vertical type, and the magneto multiple board of horizontal type. The former was manufactured by an American, and the latter by a German company. There are no manufacturers of telephone equipment in Milan.

Consumption of Meat in Germany before the War.—In 1913, according to some statistics lately published, it appears that the total output of meat from the public slaughter-houses in the whole of the German Empire under government control amounted to 2,634,712,836 kilogrammes (in round numbers upwards of 2½ millions of English tons). The animals slaughtered comprised bullocks, calves, horses, sheep and pigs. Taking the population of Germany at upwards of 67 millions, this quantity would work out at the rate of 39 kilogrammes 378 grammes per head (86·82 lbs.). To this must be added the meat of animals slaughtered privately at farms, etc., estimated at 8·069 kilogrammes (17·8 lbs.) per head, and the proportion due to meat imported in excess of that exported, which is taken at 3 kilogrammes 279 grammes (7·22 lbs.), making a total of 50·721 kilogrammes (111·84 lbs.) per head of population.

The World's Coal in 1912.—According to the Report on Mines and Quarries by the Chief Inspector of Mines, the number of persons engaged in mining and quarrying at home and abroad in 1912 was nearly 6¼ millions, of whom nearly one-fifth were employed in the United Kingdom, and more than one-third in the British Empire. More than half the total number were engaged in getting coal alone, Great Britain employing 1,072,000; the United States nearly 723,000, Germany nearly 719,000, France over 202,000, Russia (1910) over 180,000, Belgium over 146,000, Austria over 128,000, and India nearly 133,000. The total amount of coal produced was nearly 1,250 million metric tons, the value of which is estimated at over £481 millions sterling. The quantity and value compared

with the year 1911 show an increase of over 63 million tons in the output, and of over £46½ millions sterling in the value.

Cultivation by Electricity in Italy.—It is announced that some interesting experiments will be made, during the coming spring, in the application of electric power for ploughing and other agricultural operations in Italy. The trials, which will be made under the auspices of the "Stazione Sperimentale di Risicoltura" of Vercelli, and the "Società anonima Elettricità Alta Italia" of Turin, will take place on a rice farm in the Province of Novara. The trials will be open to foreign as well as Italian makers. A minimum of 5 hectares (about 12½ English acres) is fixed for the ploughing competition. Substantial prizes, as well as payment for the land ploughed, are offered. The rice-growing districts of Vercelli and Novara are particularly well supplied with electric energy, derived from the numerous rivers and torrents which flow in the Italian valleys of the Alps.

Output of Coal in Germany.—According to a telegram from Berlin, published by an Italian paper, it is stated that the total output of coal in the German Empire in 1914 amounted to 84,809,916 tons, or 16·57 per cent. less than during the preceding year. The consumption during the same period was 55,146,642 tons, or 15·49 per cent. less than in 1913. It is also stated that coke is almost exclusively being used on the German railways.

Imports of Flour and Grain to France.—According to the *Journal Officiel*, the quantity of grain imported by France during the four months ending November 30th last amounted to 5,933,162 quintals (504,169 English tons), as compared with 4,723,062 quintals (464,868 tons) during the corresponding period of the previous year. The quantity of flour imported during these four months was 653,509 quintals (64,321 English tons).

Decrease of Trade of Port of Genoa, 1914.—It was stated at the last general meeting of the Port authorities at Genoa that there has been a falling off of upwards of 600,000 tons in the movement of shipping at Genoa last year, as compared with that of 1913. This falling off is chiefly noticeable in the quantity of coal landed, whilst the imports of cotton, on the other hand, show a considerable increase.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock (except where otherwise announced):—

February 24.—W. J. Ashley, M.A., M.Com., Ph.D., Professor of Commerce in the University of Birmingham, "The Economic Position of Germany." The Right Hon. Sir George Houston Reid, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, will preside.

March 3, at 4.30 p.m. — William Poel, "Shakespeare's Profession." Sir Squire Bancroft will preside.

March 10.—J. W. Gordon, K.C., "Patent Law Reform and the War." Dugald Clerk, D.Sc., F.R.S., will preside.

March 17. — H. M. Thornton, "The Industrial Uses of Coal Gas."

March 24, at 4.30 p.m.—Lady Lugard, "The Work of the War Refugees' Committee." Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, will preside.

April 14. — T. Thorne Baker, "The Industrial Uses of Radium."

Indian Section.

Thursday afternoons:—

March 18, at 4.30 p.m. — Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army." The Right Hon. Viscount Bryce, O.M., D.C.L., LL.D., F.R.S., will preside.

April 15, at 5 p.m. — Perceval Landon, "Basra and the Shatt-ul-Arab." The Right Hon. Earl Curzon of Kedleston, G.C.S.I., G.C.I.E., will preside.

May 13, at 4.30 p.m.—M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March 2.—David Lindsay (Leader of the Elder Scientific Exploration Expedition, etc.), "The Northern Territory of Australia: Past, Present, and Future." The Right Hon. Sir George Houston Reid, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, will preside.

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced:—

Frank Baines, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. Hulme, "Patent Law."

Roger Fry, "Post Impressionism in Design."

C. H. Sherrill, "Ancient Stained Glass."

A. S. E. Ackermann, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., "On an Economical and Smokeless Grate, and on the Measurement of the Efficiency of Open Grates."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

M. H. Baillie Scott, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Fothergill Lectures.

Monday evenings, at 8 o'clock:—

Professor Vivian B. Lewes, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

Syllabus.

Lecture II.—February 22.—*Petrol Substitutes.* (*a*) Definite compounds—Benzol and alcohol. (*b*) Mixtures—How far mixtures of heavier grades of petroleum with spirit can be used. (*c*) The "cracking" of heavier fractions of petroleum into spirit—The researches upon which such processes are based, and their teaching.

Lecture III.—March 1.—"*Cracked*" *Spirits.* The effect of degree of temperature used—The use of water or steam—Surface action and its supposed effect—Processes in use—The utilisation of gases in solution to increase vapour tension—The steam engine *versus* the internal combustion engine for motor traction—Conclusions.

MEETINGS FOR THE ENSUING WEEK.

Monday, February 22...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Fothergill Lecture.) Professor Vivian B. Lewes, "Motor Fuels." (Lecture II.)

Medicine, Royal Society of, 1, Wimpole-street, W., 8 p.m. Section of Odontology. 1. Dr. Ackerley, (*a*) "Some Primary Factors in the Causation of Gingivitis"; (*b*) "Disappearance of Adeno-Fibroma of Breast after Adequate Treatment of Oral Sepsis." 2. Dr. H. Ewan Waller, "The Influence of the Thyroid Gland upon Dental Caries."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Messrs. I. Dixon and B. H. N. Ryde, "The Report of the Land Enquiry Committee on Rating."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Sir Everard Im Thurn, "European Influence in the Pacific."

Tuesday, February 23...Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Paper on "Training of the Industrial Side of Engineering."

(Western Local Section.) Park-place, Cardiff, 5 p.m. 1. Address by the Chairman, Mr. D. E. Roberts. 2. Mr. C. P. Sparks, "Electricity Applied to Mining."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Muscle in the Service of Nerve." (Lecture VI.)

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. Mr. H. E. Yerbury, "The Electrolytic Action of Return Currents in Electric Tramways on Gas- and Water-mains; and the Best Means of Providing against Electrical Disturbances."

Zoological Society, Regent's-park, N.W., 8.30 p.m. 1. Miss Jackson, "Exhibition of a Collection of Stick-Insects." 2. Dr. J. F. Gemmill, (*a*) "Abnormal Gills in the Starfish, *Porania pulvillus* O. F. M."; (*b*) "On the Ciliation of Asterids, and on the Question of Ciliary Nutrition in Certain Species." 3. Miss K. Haddon, "On the Methods of Feeding and the Mouth-parts of the Larva of the Glow-worm (*Lampyris noctiluca*)." 4. Mr. R. E. Turner, "Descriptions of New Fossorial Wasps from Australia." 5. Lieut.-Colonel J. M. Fawcett, "Notes on a small Collection of Heterocera made by Mr. W. Feather in British East Africa, 1911-12."

Anthropological Institute and the Prehistoric Society of East Anglia (Joint Meetings), at the Royal College of Surgeons, 2.30 p.m. Papers will be read by Members of the Prehistoric Society.

50, Great Russell-street, W.C., 8.15 p.m. Mr. C. Dawson, "Ouse Valley Cultures."

Wednesday, February 24...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Professor W. J. Ashley, "The Economic Position of Germany."

Geological Society, Burlington House, W., 8 p.m. 1. Dr. J. E. Marr, "The Ashgillian Succession in the Tract to the West of Coniston Lake." 2. Mr. H. S. Shelton, "The Radio-active Methods of Determining Geologic Time."

Electrical Engineers, Institution of (Local Section), Philosophical Hall, Leeds, 7 p.m. Mr. C. P. Sparks, "Electricity applied to Mining."

Literature, Royal Society of, 20, Hanover-square, W., 5 p.m. Mrs. C. C. Stopes, "Hamlet of the Story and Hamlet of the Stage."

Geographical Society, in the Theatre, Burlington-gardens, W., 8.30 p.m. (Extra Meeting.) Sir Harry H. Johnston, "Africa after the War."

Thursday, February 25...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Discussion on the "Care and Development of the Child—from the Ante-Natal Period to Five Years of Age." "Ante-Natal Period," by Dr. G. E. Pritchard; "Infancy," by Miss J. Halford; "One to Five Years," by Dr. D. Forsyth.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. P. Chalmers Mitchell, "The Struggle of Nations."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. R. A. Morrell, "Three Periods of Warfare."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. C. P. Sparks, "Electricity applied to Mining."

Friday, February 26...Royal Institution, Albemarle-street, W., 9 p.m. Rev. A. L. Cortie, "The Solar Eclipse of 1914."

Shakespeare Association, King's College, Strand, W.C., 5.30 p.m. Mrs. C. C. Stopes, "Shakespeare and War."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Saturday, February 27...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Recent Researches on Atoms and Ions." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,249. VOL. LXIII.

FRIDAY, FEBRUARY 26, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 1st, 8 p.m. (Fothergill Lecture.) PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." (Lecture III.)

TUESDAY, MARCH 2nd, 4.30 p.m. (Colonial Section.) DAVID LINDSAY (Leader of the Elder Scientific Exploration Expedition), "The Northern Territory of Australia: Past, Present, and Future." The RIGHT HON. SIR GEORGE HOUSTON REID, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, will preside.

WEDNESDAY, MARCH 3rd, 4.30 p.m. (Ordinary Meeting.) WILLIAM POEL, "Shakespeare's Profession." SIR SQUIRE BANCROFT will preside.

Fellows are requested to note that the hour of the Ordinary Meeting on Wednesday next is 4.30 p.m. instead of 8 p.m.

Further particulars of the Society's meetings will be found at the end of this number.

FOTHERGILL LECTURES.

On Monday evening, February 22nd, PROFESSOR VIVIAN B. LEWES, F.I.C., delivered the second lecture of his course on "Motor Fuel."

The lectures will be published in the *Journal* during the summer recess.

CANTOR LECTURES.

The Cantor Lectures on "The History and Practice of the Art of Printing," by R. A. PEDDIE, Librarian of the St. Bride Foundation Typographical Library, have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor and Howard Lectures which have been published separately, and are still on sale, can also be obtained on application.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, February 11th, 1915; LIEUT.-COLONEL SIR FRANCIS E. YOUNGHUSBAND, K.C.I.E., LL.D., D.Sc., in the chair.

THE CHAIRMAN, in introducing the reader of the paper, said he was one of the hundreds of British officers serving on the 3,000 miles of the Indian frontier in extremely varying conditions. In addition to that courage and military training which was to be expected in military officers he also had a very large share of tact, resourcefulness and sympathy in dealing with all kinds of different people—in fact, all those qualities which were so conspicuously absent in our opponents across the North Sea at the present moment. The author served for many years in the Assam Military Police, and in that capacity had exceptional opportunities of becoming acquainted with that extremely interesting piece of country and people which he would describe in the paper. It was a country in which he (the Chairman) personally took very great interest, because he tried, when he was at Lhasa, ten years ago, to send down an expedition to solve the problem of the identity of the Brahmaputra River with the River Tsanpo, which the expedition crossed in Tibet on the way to Lhasa. It was a most remarkable circumstance that that huge river should be able to find its way across that gigantic range of

snowy mountains, the Himalayas, which had recently been proved by the explorations of Captain Bailey, Captain Morshead, and others.

The paper read was —

TRIBES OF THE BRAHMAPUTRA VALLEY.

By Captain Sir George Duff Dunbar, Bt., I.A.

The part of the world that we are going to consider this afternoon is a section of the wild country lying between the Main Snowy Range of the Himalayas and the plains of Assam. Through this region flow two great rivers —the Brahmaputra and the Subansiri. With the Brahmaputra, which is the Tibetan Tsanpo, the Abor Siang, and the Assamese Dihang, the names of Kinthup and of two British officers —Bailey, of the Political Department, and Morshead, of the Survey of India—are indissolubly connected.

There is barely time to describe the country, and run quite briefly over some of the more salient characteristics of the Abors and Galongs, two of the tribes settled in the highlands drained by the Dihang; but it should be realised that to east and west in very similar country dwell other peoples, probably of the same stock, who are either, as the Akas, in a more advanced state of civilisation, or, like the Mishmis, in a yet lower grade of culture.

The country rises in a series of ridges from the plains. Behind the foothills Nature has flung a tangle of high jungle-clad spurs, with a corresponding labyrinth of deep-cut valleys beneath them. The foothills of clay and shale that make none too easy going are, of course, entirely dwarfed by the country immediately south of the high snowy peaks that guard the passes into Tibet. Anyone who has seen this region can whole-heartedly apply to it Service's lines upon the Yukon :—

It's the cussedest land I know,
From the big dizzy mountains that screen it
To the deep death-like valleys below.

But between the clay slides and razor edges of the foothills and the tremendous cliffs and cañons to the north lies a most welcome intermediate zone. Here, in the heart of the hills, the spurs recede and the country becomes more open. The alluvial terraces that mark earlier levels of the Dihang and the rich straths up the Siom river are industriously cultivated and support large groups of prosperous communities. Similar conditions exist in the Dafla country. The Mishmi highlands do not improve in the same way on a closer acquaintance.

The two principal points that strike the traveller are the extraordinary closeness and luxuriant growth of the jungle that stifles the whole country, and the unpleasant fact that the miles stand almost on end. A normal road section looks like a bad enteric fever chart. When one has got into sufficient training to be able to admire the view from the crest of a ridge or at a clearing, another feature becomes evident. This is the stupendous depth to which the Dihang river has cut its bed (it is sometimes three thousand feet below the path) and the remarkable twists it makes in its course through the hills. There is one place where it changes its direction to every point of the compass in a space of under six miles. One remembers the mighty river best as a great grey-green snake, flecked with the foam of its rapids, writhing between great walls of rock on its long journey from Western Tibet to the Bay of Bengal; and, if I may say so, worst as the rather turbulent carrier in flood-time of a badly waterlogged bamboo raft. This perhaps is ungrateful, as the mahseer and boka that swarm in its water give the most excellent sport.

The magnificent pine lumber that is swept down the river comes from Tibet itself, or from the country immediately below the Main Snowy Range. Up the main valley, even on the highest features, we found no pines, cypresses or tree azaleas and rhododendrons much south of the twenty-ninth parallel of north latitude. Yet immediately to the east, in the Mishmi country, the first march out of the plains brings one to the azalea and rhododendron forests, and the pines come down almost, but of course not quite, as far south.

The forests of the Abor country vary, naturally, in character according to their height above sea-level. This can best be illustrated by some notes made on the ascent, at the end of May, of a ten thousand foot hill on the twenty-ninth parallel. The hill, locally known as Dino, was an isolated feature rising above the Dihang, in a perfectly symmetrical cone, and ridiculously easy to climb.

A shot at a takin on the higher slopes and the prospect of a wonderful view from the summit were hopefully anticipated. The entire absence of water for the last five or six thousand feet precluded all chance of big game, and a persistent drizzle and sleet while the party remained at the top prevented an

enjoyment of any more view than that of wet and icy-cold shelters of pine-branches under the lea of limestone slabs, varied by an inspection of the patches of snow that yielded our only water supply.

But to return to the climb. The zones of vegetation were in clearly marked belts. To nearly four thousand feet thick luxuriant undergrowth and parasitic jungle choked the forest, then came brakes of thin bamboo and low bush jungle at the foot of the trees. This was succeeded by ferns and the stony outcrop became more noticeable. All Dino is a whitish crystalline limestone. The trees, too, had changed their character and we were among the azaleas, then in bloom, immense blossoms of white filling all the air with fragrance. Above these again the rhododendrons began—first the red, then an occasional tree dotted with little bunches of clear pink flowers. Most of the tree-trunks were quite bare, the azalea stems a rusty brown, making a fine colour effect. At eight thousand four hundred feet we found the first cypresses, and the rhododendrons—some of them—had yellow blossoms. We saw trees with leaves a cross between the foliage of the elephant apple and the true rhododendron all in flower, with bunches of white canterbury bells. At this height the trees were coated with thick moss. At nine thousand feet, climbing over great square blocks of limestone, we came across a bush or two of holly among the cypresses. Then a final scramble brought us up on to the summit. A narrow heath-covered ridge, strewn with limestone slabs, and dotted with low scrubby rhododendron bushes and azaleas all purple or pink, then in flower, dwarf cypresses with torn branches, and flat-topped as if shaved by the tremendous winds. The lower forests are bright with orchids that cling, like the ferns, to the tree-trunks, but here at more than ten thousand feet we found Sylogyne, hardiest of all orchids, for it must spend more than half its life under the snow.

In the lower forests clumps of bamboo and wild plantain are prominent features. The undergrowth includes highly poisonous stinging shrubs and nettle and a very thorny cane that we call "baint." In marked distinction to the country to the east and west, there is very little game in the Dihang valley. The lower zones are overhunted. There are a few serow and an occasional tiger; khalij pheasants, jungle-fowl and hill partridges are not uncommon. The country makes up for all this by harbouring the hosts of leeches, poisonous flies, mosquitoes and ticks that rejoice in a rainfall estimated at about 800 inches in the year.

So much for the country. We may now consider the people settled there.

The type is distinctly Mongoloid. It might be rash to claim kinship for them with the nomad totemistic tribes of Central Asia, such as the Yakuts, but systematic investigation for over four years has led me to the conclusion that the Abors and their brethren migrated from the Tibetan side of the Himalayas into the Dihang valley. Writing is unknown, so ancient inscriptions do not exist, but such myths as survive amongst the village medicine-men all point to a northern origin. Successive waves of migration seem to have pushed the earlier settlers south and then west. So we now find the Abors and Membas (or Monbas), who came last of all, in possession of the valley, with the Galongs, Hill Miris and Daflas away to the west. The Membas, we know, came over about a hundred years ago, and founded their colonies by ousting the wild Tangam clan of Abors, then established north of the twenty-ninth parallel, from the most fertile portions of what is now known as Pemakoichen. Similar Memba migrations in recent times have occurred further to the west.

Only those hillmen who are in touch with Assam recognize themselves as "Abors." This name is derived from the Assamese *a-bori*, unfriendly, which clearly indicates a reputation won from the seventeenth century onwards by incessant raids and forays. They will admit to belonging to a clan, such as Minyong or Padam, but prefer to call themselves men of their own village, or of its parent community. The village is the true political unit, but even here the different septs that live in it do not always have community of interests. One of the reasons for so parochial an outlook is to be found in the extravagant method of cultivation employed by the hillmen that obliges all villages, other than the prosperous allied groups in the richest localities, to establish themselves at a considerable distance from each other.

Till the close of the eighteenth century all the tribes west from the Aka country to the Dihang were grouped together by the Assamese Government under the name of Daflas. They are all definitely akin, in their ways and general appearance. Nor, apart from the distinctive dialects spoken in the Dihang valley, is there much essential difference in their language. It is interesting to note that the Limbus of Nepal, from whom we draw some of our sturdiest recruits for the Military Police, have much in

common in religion and even in language with the Abors.

Photographs give the best idea of the appearance of the people. As their complexion varies, from a very dark brown near Assam, to almost white high up the valley, and as some clans, such as the Padam Abors and Memong Galongs, are frequently of an unusual height for hillmen, it is difficult to generalise in describing them. But one can say—generally—that they are a sturdy race, with straight black hair and dark brown eyes. Infanticide has never been admitted to me, but on only one occasion (if I exclude a headman with six toes) have I come across any deformities. These were two women dwarfs in Membu, a Padam village, both of whom were fully developed and healthy.

There are among the more southern clans two methods of hair-dressing. The typical Abor cut for both sexes is to shave all round the lower part of the skull, leaving a thick cap on the top of the head with a straight-cut edge above the ears. The Galong men generally cut their hair more or less short all over, while their women part theirs in the middle, and tie it in a bun at the back, plaiting the tresses nearest the forehead. This is similar to the way in which some Kongbo women whom we met did their hair. The wildest hillmen we saw wore their hair quite long and loose.

There is not time to give details of their clothing. To take the men first: it ranges from the grass sporan, that is frequently deemed sufficient on a wet and muggy day, to thick woollen chocolate-coloured coats and skins of deer or takin. All the woollen stuffs are imported from Tibet. Cotton fields were seen the whole way up the Dihang, and the cloth made from this is dyed black by the northern clans; it is left white in the southern districts. The thicker skirt-cloths that the women wear are woven in blue, red, white, green and sometimes yellow, by the communities closest to the plains. The men of one clan almost universally wear an excellent short coat of what looks like blue serge. One article of dress remains constant, the "bowler"-shaped hat, generally of fine cane-work, but sometimes of hide. This is gaudily bedecked with bunches of hair dyed red, feathers, or hornbill beaks, according to the wearer's fancy.

Little boys and youths frequently go about in a state of nature. Little girls always wear a disc or two as a beyop. The beyop is a girdle of a varying number of white metal discs (they are rarely of brass) of graduated sizes, that is worn exclusively by Abor and Galong girls until the birth of their first child. The legend of its origin, the gift of a god, recalls certain tales of Greek mythology.

It is curious that among the Hill Miris and Daflas, who are almost identical in appearance, language, customs and beliefs with their eastern neighbours, the beyop is unknown. Their more well-to-do women wear over their short skirts a cane or leather belt adorned with rather elaborate metal bosses.

You can see from this photograph how the beyop is worn. The number of discs varies in the different clans. The Minyong young women jangle to the tune of as many as thirteen in their walks abroad, but eleven or nine is more usual. Galong women generally wear fewer discs than this. In the north five, and amongst the wilder clans (where metal is scarcer) three discs serve their less exacting needs. In the more remote districts especially, the beyop is in summer not uncommonly the only wear.

Apart from this, the costume of the ladies has been seen to range from the Arcadian simplicity of a skirt of leaves to a couple of gaily-coloured cloths, one worn as a petticoat, the other wound tightly round the upper part of the body. In very wet weather they may throw a small cloth over their heads, but no women have ever been seen wearing the cane hat, which is in fact an article of kit for the fighting man.

In the way of ornaments both men and women wear strings of blue or green porcelain beads. Some of these necklaces contain bits of shell, or metal-work, from Tibet. The best necklaces are handed down as heirlooms, and are of considerable age. Earrings of white metal or bamboo are worn by men and women alike. Both sexes wear rings of cane round their legs below the knee, and plaited cane belts that are occasionally worked in neat conventional designs, in white and black. Abor women wear anklets of plaited cane-work bands. Galong women wear broad, flat bands of brass round the ankles. These are put on in childhood, and are not taken off again, except as a mark of disgrace. The Galong matron consequently regards her hideously misshapen leg with equanimity, and will endure considerable pain from an over-tight anklet with composure.

Cicatrisation is unknown. Only some of the tribes tattoo. This is, moreover, a decaying practice, and is chiefly followed by the women. Skilled artists in tattooing, if one can apply the term to a people almost entirely devoid of the artistic sense, are given a definite wage, either

in kind or in labour. The designs, which take the form of lines, circles, and crosses on the mouth, cheeks and forehead, and something like the hieroglyph for the Nile on the calves of the leg, are made in charcoal with a sharp bamboo needle.

On a journey the hillman wears a big ruksack with, as a rule, a rainproof, fibrous cover, generally dyed black. In this he carries his food supplies of rice tied up in packets of leaves, a meal in each. Smoked birds, bits of squirrel or rat on skewers, and such small deer are taken as delicacies, and chillies and perhaps ginger to vary the monotony of his boiled rice. In the Mishmi hills millet—not rice—is the staple food. His pipe and tobacco are carried, like his quartz and steel (flint is unknown in his hills) in pouches of skin that he hangs about him. He is never separated from his *dao*, which is the broad-bladed dirk indispensable to the wild man of the woods. Generally he has a bamboo staff, and invariably he slouches along, puffing his acrid tobacco, with his dog somewhere on ahead. Abor dogs are usually black with points, and look like badly-bred terriers. We must remember, as the hillman invariably does, a bamboo cylinder or gourd full of *apong*, as he calls his beer. It is a mild intoxicant brewed from millet seed. Every hillman, and woman and child, too, is frequently "disposed" to put the gourd to his lips, and expects all friendly white visitors to do the same. I may say here and now that the stuff varies from the quality of quite a good hock to the depths of nauseousness. On a hot day, after the usual stiff climb to a village, it can be most welcome, even from its forbidding receptacle—a pipe-shaped gourd dipped many times and oft, for all and sundry, into the large gourd that holds the brew.

There are two types of village. This photograph of Kombong, a Galong village, shows the haphazard way in which the houses of one type are built. In Minyong Abor villages each sept builds its houses in a continuous line. This is Komsing village, and the excellent photograph was taken and given to me by Mr. Stanley Kemp, of the Indian Museum, who accompanied the Abor Expedition of 1911–12. It was in this village that Mr. Noel Williamson and his party were massacred in the spring of 1911. Villages are, as a rule, perched on a ridge or plateau some little way from their fields. The approach to the village along a sharply ascending path is marked by an arch or gateway, flanked on either side by the rather poor defences afforded by a palisade or low stone wall. Sometimes visitors find a succession of newly-made archways of green boughs and plantain stems over the path. These are not triumphal arches erected by an enthusiastic entertainment committee in honour of the representatives of His Majesty's Government. They are put up by a superstitious community, who devoutly hope that even if they are unable to evade a highly undesirable visitation, they can at least make arrangements to exclude the still more distressing demons of ill-luck and disease that always accompany strangers from afar. So these arches bristle with imitation arrows and *chevaux de frise*, and on them are skewered sacrifices of dismembered dog, pig, or even cattle, according to the custom of the clan and wealth of the community. Nor, on the other hand, should the traveller place a false construction upon the volley of bits of plantain stalk that may follow up his departure from the village. These are thrown to drive out any malevolent spirits that may have penetrated the defences when the party arrived.

Within the bounds of the village, and well below it, is the burial ground, a cluster of tiny huts that are built over the graves.

The immediate vicinity of the village is proclaimed by the barking of many dogs, the shouts of the inhabitants, and the glimpses of the thatched roofs of the granaries among the jack-trees that the hillman so carefully tends. By this time, of course, the party has been met by a solemn deputation of all the most prominent citizens, attended by their womenkind with the inevitable gourds of *apong*. They also bring little baskets of doubtful eggs and very skinny and ancient fowls—the customary offering to evil spirits.

All hill houses are raised off the ground on piles or, in the north, stone walls. They are plank or bamboo-built structures with open platforms in front of the main entrance. The roof is thatched with cane leaf that lasts about three years. There are no windows, and the roof comes down very low, to keep the rain from driving through the walls. The houses vary enormously in length. A Mishmi house, built to accommodate perhaps a dozen families, is over one hundred yards long, and is divided up into regular suites of apartments. The Subansiri hill houses are not as long as this; they shelter, perhaps, two or three families. The squat Abor and Galong dwellings are built for a single household, not infrequently as a sort of wedding present from the village to a newly-married pair.

In Abor and Galong houses the one big room

is about 30 ft. long by 24 ft. wide, lit up by the fire flickering on its square stone hearth—and ventilated not at all. The portable possessions of the household are kept on a large tray that hangs from the rafters. The master of the house sleeps near the door, and the rest of the family keep on the further side of the fire. Trophies of the chase and menus of bygone banquets, in the form of heads of cattle, hang on the walls. I have been entertained, in a Naga house, where the heads were of a much more interesting kind—but that is a story of another frontier altogether.

Besides the family dwellings two other buildings are to be seen in an Abor village. The most important of these is the Moshup, a long building with many entrances that is both the village council chamber and the barrack in which the young men of the village sleep at night. It is generally in a central position. The other building, which is not always to be found in their villages, is a dormitory for the unmarried girls.

The smith works with his bamboo bellows and his clay and wax moulds in his own house. Industrious families are to be seen cleaning and spinning cotton, or weaving, or, perhaps, making basket-work of cane, or mats of screw-pine leaves on the platforms of their houses; whilst the old men, clad in their fluffy cotton coats, sit about and smoke and grumble—as they do in other places. Sugar-cane and other little luxuries (that include opium in the southern hills) are grown in small walled or fenced plots. Jack-fruit and orange-trees abound in the lower villages, and further north we find peach-trees. On the outskirts of the village are the granaries, like miniature houses, and all provided at the top of their supporting piles with wooden discs to keep out the rats.

The water supply is run into the village from the nearest perennial spring. In this, and in his bridges over the larger rivers, the hillman displays engineering ability of a high order. Bamboo aqueducts entailing a skilful alignment are common throughout the hills; but the Padam Abors seem to delight in building their villages on sites as remote as possible from water. Membu, in the foothills, is an excellent example. The spring supplying this large community is tapped on the face of a cliff more than 100 ft. above the level of the main groups of houses. Down the face of this cliff the water is run through two carefully graded spiral pipes. From there the aqueduct runs for 1,200 yards to the village green.

It is not possible to imagine a more democratic organisation than the system followed by these hill tribes. In the first place the village, and not the clan, is the unit. The headship of the village is not hereditary; and the headman himself only remains the leader of thought and action so long as he voices the feelings of the majority in the rather noisy meetings that are held in the Moshup. Occasionally, of course, a man of very strong personality is able to control his own community and exercise considerable influence over the neighbouring villages.

A far more retiring individual—from the gaze of inquisitive foreigners—is the medicine man or woman (for priestesses are not uncommon among the Abors). The Galong priesthood is only open to men. The mirü, as he is called, by performing the rites of sacrifice and divination exercises a considerable influence and, unlike the headman, is not liable to supersession. He is therefore a power in the village. The Galong mirüs, moreover, are believed to possess powers of an unusual kind. The most formidable of these is an ability to curse his enemies to death from a lofty platform.

The cultivation of corn in sufficient crops, in the wild jungle-clad hills that these people inhabit, is a problem that entails immense labour. This problem is rather unsatisfactorily solved by a system of agriculture known as jhuming. Large tracts, within the recognised area owned by the village, are cleared, and the felled wood and undergrowth burnt. These cleared tracts are divided up among the different households, who proceed to sow rice and millet broadcast over their holdings. There are two harvests, one in May, the other in September. Wet rice cultivation is unknown. Chillies, tobacco, cotton, Indian corn, pumpkins and cucumber are also grown. But in so wet a climate weeds, grasses, bushes and saplings grow apace, and after three or perhaps four years the villagers give up the unequal contest with nature and seek fresh woods to turn into pastures new. They may perhaps return to the same ground in fifteen or twenty years, but the system is a wasteful one and demands a wide range of country. This keeps the villages rather far apart, and appears at least to contribute to the isolated policy and lack of cohesion noticeable through the hills. Exceptions are found in the highly cultivated and densely populated straths of the richer valleys. But everywhere the methods are primitive, and a dao and a pointed stick are the only agricultural implements they

know. The hills are cultivated up to a height of about 5,000 ft.

The most important live stock are the herds of domesticated mithan (*Bos frontalis*). These belong to definite households. The various septs mark their cattle by cutting oblongs and triangles out of their ears. Mithan are not milked and are only killed for ceremonial feasts. This is done by strangulation with a rope. A pig is strangled between two sticks and a bamboo skewer run through its heart. Pigs and fowls are fairly plentiful. Goats are found in the Galong country, but are not kept by the Abors. The hillmen eat eggs. As a matter of fact, to eke out indifferent harvests they ransack the streams and the woods for fungi, insects of the beetle and locust families, prawns, birds, and rats. In the rivers huge fish traps are set. These are either baskets tied on long cane ropes to the end of bamboos, or dams built out across the river. The fungi are boiled several times as a precautionary measure. Many of the insects are eaten raw. Birds and bits of meat are thrust on to a skewer and either burnt for a little or smoked. Rice is boiled rather neatly. An internode of bamboo is filled with water. Rice done up in packets of leaves is put into the cylinder which is then rested over a brisk fire. The bamboo is turned at intervals, and when the sides are charred all round the rice inside is found to be cooked.

The people are keen hunters and trappers. Game is driven and shot with poisoned arrows. Many kinds of traps are used, from the formidable bow and javelin contrivance with its trip-wire to release the spring, and the staked pit for the larger animals, down to the stone, supported on sticks under which they catch rats.

The tribes are by nature unwarlike. Individually they can be brave enough, but lack of cohesion reduces their operations to raids and the most minor of onfalls. Like all primitive hunting races, all the male element of the population carry a bow, spears, and perhaps a long sword in addition to their dao, which is an absolute necessity of life to the dweller in the jungle. And all boys are taught to shoot with the bow. Guns are very uncommon, though an occasional tower musket is to be found in the lower villages. In the northern villages prong guns are not quite so rare. The long swords are brought down from Tibet, along the salt trade routes.

The chief weapon is the iron-shod bamboo bow with a cane string. This is effective with all-bamboo arrows up to 180 yards, and I have known it carry 250 yards. The bamboo point is hardened in the fire, and may be dipped in aconite or croton poison. The war arrow, which has a heavily poisoned iron or bone head, has a much shorter range. The shaft is deeply notched so that the head may break off and remain in the wound. All their arrows are fletched straight—not spirally—with cane leaf. The arrows are carried in a bamboo case provided with a lid and fitted with an outside pocket for spare strings and a bracer guard of cane.

Their long spears are more for show, or use as an alpine stock, than anything else; and, unlike the Naga javelins, are never thrown. The spear-head is small and is ornamented with a tuft of hair, dyed red.

When fighting against British troops great reliance is placed on immense and elaborately built stockades. One of these was found by a punitive column to be 2,000 yards long, 10 ft. high, loopholed and shell proof. These stockades are admirably sited. Their engineering skill is also devoted to the construction of stone shoots. These are generally suspended high above the path—at a ticklish place for choice—and are given a clear line of descent. Those placed 40 to 100 ft. up are the most awkward for a shower of rocks bounding down a steep hillside from 1,000 ft. up may look formidable, but is almost certain to miss the roadway altogether. When inter-clan differences are being settled cut bridges and blocked roads play a prominent part.

Reference has been made to the industry and engineering skill of the people. These qualities are combined in the construction of the tubular cane bridges with which they span the Dihang.

This bridge (below Komsing) has been destroyed since these photographs were taken by Mr. Kemp. But there are quite a number of similar feats of engineering higher up the river. This particular bridge was built in about three weeks. It was 786 ft. long and was at the entrances 130 ft., and in the centre 50 ft. above the winter level of the river. In the construction of these bridges several strands are floated across, pulled taut on the trees selected on either bank as uprights; and on this the bridge is made. They are very flimsy, have frequently no semblance of a roadway and swing most unpleasantly in a wind. The Abors always cross these bridges in step, singing as they go.

It has already been observed that writing is unknown. This is accounted for by the Padam Abors in a rather curious legend. Long ago, the story runs, the Supreme Being gave his

precepts to man. To the cities of the plains he gave tables of stone, to the people of the hills he gave a sheet of parchment. But with characteristic improvidence the hillman, to whom the precious skin was entrusted, being sorely pressed by hunger, ate it.

To supply the lack of writing, messages of the greatest importance are occasionally sent in the form of stones, rice, chillies or charcoal tied up in small baskets. These messages seem to be confined to protestations of friendship or cartels of defiance.

Chillies and charcoal mean the absolute defiance of a mind burnt like charcoal, with thoughts as fiery as the chillies accompanying it. An embassy was once sent to us by a hill community to proclaim its peaceful intentions. These, I may say, were found afterwards to be sincere, though they were doubted at the time. The spokesman produced a bag and drew from it a sword-blade bent double. "This," he said, "is the sentiment of the Gam towards the Government; and this (producing a spear-head, with a broken point) is the sentiment of his kinsman and co-Gam. This (producing a round pebble in a cane-work basket) is the heart of these two, which they send clean of reproach. This (producing an old metal charm), being made from an element of the earth, bears witness to the straightness and truth of the mind and words of the Gam and his kinsman."

As a warning to cattle thieves, "signboards" are erected on the path from the offender's village. They are made of cane and bamboo. A stick represents the thief, who is exhibited in a miniature stock—the ultimate fate of the cattle thieves. The signboard is studded with a number of slips of bamboo representing arrows to indicate the feelings of the aggrieved owner of the stolen animal.

There is no time to touch even briefly upon the question of language. But there is, I understand, some similarity between the form of numerical adjectives used by the Abors and the Burmese. Notation is very simple, in tens, ten and one, and so on, up to 100. But the hillman's ideas of the higher numbers are exceedingly vague. He likes to be able to count upon his fingers and toes, or else to produce little bundles of sticks.

The Galongs and Abors are exogamous, and intermarriage between members of the same sept is tabu. Polyandry is unknown. Polygamy occurs only when the head of the house is well enough off to acquire more than one wife. The men make really good husbands, and prior to marriage and the setting up of a house of their own, court the girl who takes their fancy. The Abor lady wears as an engagement ring a loop of cane suspended from her neck. Sometimes a ring is broken and each keeps half. The young man is expected to give occasional presents of squirrel skins to the girl's parents, and has to pay them a varying number of mithan when he takes her away from her father's house.

The present religion of the hillmen is polydemonism. The tribes propitiate the malevolent spirits of earth, air and water by varying rites, and call them by different names. Sacrifice of animals and libations of apong are held to appease these demons when sickness and death manifest their displeasure. For instance, if, when the jungle is being cleared for cultivation, anyone falls sick, it is attributed to the anger of the local demon at the destruction of his home, and propitiation is offered, generally by sacrificing a pig. Time will, I think, just permit me to describe the rites performed during the illness of a woman. A large pig is sacrificed in the village to the angry spirit held to be responsible. The second act takes place in the jungle. Here an altar, consisting of two upright poles connected by horizontal bars, is erected. To this altar is tied a basket containing nuts and plantain and bamboo-leaves. The party making the sacrifice bring a black hen with them; to one of its legs are fastened threads of different colours, and to its other leg is bound the leaf of a certain jungle plant. The hen is then thrust through the bars of the altar and allowed to escape into the jungle. As it is let free the following words are pronounced: "O Nipong, I have marked and dedicated this hen for you. Take it and cure the sick one." If the hen comes back the omens are unfavourable. After releasing the hen a dog is killed and the carcass suspended from the top bar of the altar. The spirit of this animal is formally handed over to the demon, a shield of leaves is placed over it, and the party go home to await the omen of the fowl. I think one of the most interesting features of their religion is a firm belief in the future life of both men and animals.

Sometimes in sickness branches are waved about or stuck into the ground round the sick man's house. At other times the medicine-man organises religious dances by the girls of the village.

Sacrificial rites are observed both at seed-time and harvest, when pigs and fowls are killed and altars are set up.

Throughout the hills a tree, known as the holok, is regarded as the abode of the Wood Spirit. This demon is believed to assume human shape, and appearing in the form of a kinsman from some distant village lures some unfortunate villager away into the jungle. So when anyone is missing and cannot be accounted for, the people of the village go out into the jungle armed with swords, bows and arrows to look for him. They go to the holok tree and say: "O Holok tree, give us back our brother and we will make you a sacrifice." And then, to compel the holok tree to urge the spirit that dwells within it to restore its victim, they hack at the tree with their swords and shoot arrows into its limbs. They then go home and await the return of the wanderer. Hope is not abandoned for about two months. If the man comes back a mithan or pig is killed and eaten at a sacrificial feast.

When a death occurs a maximum of three days elapses before burial, and a ten days' tabu is observed by the household. A grave is dug and lined with branches. In it is placed a platform, and on this platform the corpse is laid, knees drawn up to its chin, and the hands on its breast. Generally there is a pent roof over the body, and on this the earth is thrown. The body is provided with a grave cloth, a porcelain bead necklace, and a brass plate or pot. A little hut is built over the grave, and in this a fire is lit and kept burning for a period that varies from three months up to a little over a year. Apong and rice are left at the hut. On the hut itself, or on a fence erected close to it, are hung the weapons of the dead man, and perhaps some heads of mithan and serow, or, in the north, takin. I have seen in certain tribes gourds hanging to represent the heads of the men a dead warrior has killed in fight, and this is the nearest approach to the exhibitions of the head-hunting Nagas that have been noticed in these hills.

From fragments of mythology that have been collected, it is gathered that the gods were not consistently malevolent, and there still exists a vague belief in an all-great and all-loving deity: but the dominating belief is in the existence of an unseen world inhabited by the malevolent spirits of nature. The souls of all human beings and animals go to the demons who deprived them of life. When animals are sacrificed their spirits go to the deity to whom they are devoted, but the cattle and pig killed during the funeral ceremonies are believed to accompany their owner, and it is for his use that his weapons, cooking utensils and some food are placed beside his grave. It seems, tacitly, to attribute life on another plane to his inanimate possessions. Other races, from ancient Egypt to the Red Indians of the present day, afford parallel examples.

The Galongs stated that if anyone who is dead is seen in a dream, it is believed that the soul has left the companionship of the spirit who deprived its earthly body of life, and has migrated to some other spirit. It is not clear whether this mutation brings the soul into the presence of the shadowy Supreme Being. It is, however, evident that the doctrine of re-incarnation is unknown.

The religious beliefs of the Abors, especially in the north, to some extent betray points of similarity with the religion of the Membas of Pemakoichen. I speak subject to correction, but I gathered, in the course of a visit to that district, that the fundamental idea in each case was the propitiation, through fear, of malevolent spirits. The features of Shukia Thoba and his attendant satellites in the Lamaserais were simply devilish, and the monks extort as much wealth as they can in money and kind by working on the superstitious fears of the country-side. Of course, occasionally, as at Marpung (where Kinthup was befriended by the late Abbot), Sakya Muni sits, a shining golden Buddha with his calm peaceful face, but the main difference seemed to lie in the fact that the Memba religion was overlaid with such ritual and accessories as wealth and a certain amount of culture could give, whilst amongst the Abors it was not. Setting aside the wild Abors of the Tangam clan, who inhabit the more inhospitable parts of Pemakoichen, it may not, perhaps, be out of place to touch briefly on such religious customs of the Angong Abors that can be traced to the influence of their Memba neighbours. Some of these customs are to be found further south. Near one village we saw a large stone covered all over with triangular plaited cane mats, distinctly resembling the images of Buddha that are plastered over the rocks further north. Like the Memba, the Abor believes in the efficacy of boughs planted round a house in time of sickness. In one Memba village high stout posts, connected by long cane ropes, were identified with the worship of the Tibetan diety, Lhamsal. Similar manifestations of piety were seen in several Angong villages. In Janbo village rudely-made figures were fastened to the tops of masts, a feature that may be compared with the worship of the Bhotia god, Dhurma. This had its counterpart

in a most realistic scarecrow seen outside one Memba village, and overlooking the Tsanpo more than 2,000 ft. below. It had been given black clothes and provided with a bow and arrows. This, we were told, was to guard the community against the river god—a distinct echo of the Abor folklore far down the valley. In cases of sickness the Galongs set up an image in the supposed likeness of their most powerful deity. This image is about 4 ft. high, and is made of leaves on a bamboo framework. It is given a cane helmet, and leaves are arranged to represent clothing.

Attention might, perhaps, be drawn to the fact that both Abors and Tibetans strangle the cattle they sacrifice. There is also some resemblance between certain Mishmi and Abor dances and the accounts I have read of the Lama dances. I did not myself do more than see the devil masks of *papier maché* with their tiaras of miniature skulls that are sometimes used on these occasions.

Save for the fact that a regular import trade in woollen coats, salt, *dankis*, and other Tibetan metal-work comes down through Bori and Memba intermediaries to the Galongs and Abors, Tibet exercises no influence, direct or indirect, upon the country under discussion. Travellers are not encouraged, as Kinthup discovered thirty years ago. Abors from the upper part of the valley are at times employed as coolies in the caravans that cross the main passes, but general intercourse between the different Abor clans is so slight that the lower Abors know nothing whatever about the country higher up. We consequently heard some wonderful travellers' tales from the Abors living near the plains. I noted these at the time, and it was interesting, later on, to see in what way they had originated.

We were told that the upper part of the main valley was inhabited by savages, with heads growing straight from their shoulders, who were consequently unable to look up (unless apparently they lay down on their backs). To this fortunate circumstance was attributed the escape of the daring adventurer among them who lived to tell the tale. It was gravely asserted that he climbed up a tree to evade his neckless enemies, and subsequently escaped. We found that the Tangam people below the great gorge of the Tsanpo are afflicted with appalling goitre, and that their appearance:

Dew-lapped like bulls, whose throats had hanging at them
Wallets of flesh,

may well have given rise to this quaintly mediæval story.

Another tale of a fortunately unknown race, called Mimat, described how they existed in bleak wind-swept caves upon the flesh of men. But the "anthropophagi that each other eat" turned out to be Tibetans; their caves were the rest house caverns found on the routes over the high passes, and the charge of cannibalism was due to a most erroneous impression of their own, or *Lepcha*, funeral ceremonies. As a matter of fact, in accusing their unknown neighbours to the north of cannibalism, the Abors err in good company. The charge is as old as the thirteenth century writings of the Franciscan missionaries, and as new as the travels of Sarat Chandra Das.

Abor folklore is not easy to collect. The medicine men who keep the myths alive are distinctly reticent, but from such tales as have been collected one or two examples may be of interest. And with these I will end my paper.

At the beginning of time gods and men lived together upon the earth. And there fell a great distress upon all, because there was no water, and gods and men alike were lean and thin. But it was noticed, with much wonder, that the rat was always sleek and fat. So one day a man followed the rat and tracked it to a big stone, under which it disappeared. When it came out again it was all wet with water, and visibly refreshed. So the man went back and told what he had seen. But when the men came with such tools as they could gather to break the stone and get the water for themselves, they found that it was too hard—so hard, indeed, that it broke the tools they had brought with them. Then the god Debo Kombu took his bow and shot at the stone with an arrow, and a trickle of water, the stream of the arrow, came welling out of the rock. And that is the reason why Debo Kombu is worshipped with his bow and his arrow to this day. But only a tiny flow of water ran out of the stone. So the god Nurupur took an axe and broke the stone, and the water gushed out freely over the thirsty earth. And he, too, is worshipped for ever in the water he gave to gods and men. The interest of this myth lies in the portrayal of conditions so utterly different to the country the Abors now inhabit—where countless streams and a stupendous rainfall are the most prominent features.

Once upon a time Fire fought Water. And all things growing in the jungle, green things to whom water was life, helped Water. So the water rose steadily out of its bed in the valley

below and followed Fire up and up the mountain side. And it rose and rose and covered all the low hills, and filled all the valleys. So Fire fled up to the top of the highest mountain, and there it flickered, for it could go no further. At last the Water was lapping the topmost peak, to which Fire had sprung. Then, just as Water began to break over the very top of the mountain, and it seemed as if Fire must be quenched for ever, it darted as a last refuge into the heart of a stone, and has lived there ever since to be at all times the servant of man. And then Water sank and sank down to its bed once more.

Now, in those early days, the world was scorched by two suns and everything was burnt up, and the fields were hard and dry and the harvests miserable and scanty. So all the people in their distress cried out for someone to lessen the fiery heat. Then the archer-god took his bow and bent it mightily, and sped an arrow into the eye of one of the flaming suns. So the wounded sun died and became quite cold, but it still gives light, and we call it the moon. And the splinters that the arrow made when it struck the sun flew out all over the heavens and became the stars. This is the Abor legend.

The Galong myth tells us of only one sun that was hit by the archer-god, which went and hid under the earth. And the land was plunged into darkness, and a great fear fell upon all. So men went to ask the sun to appear again. But the sun was angry and remained hidden below the earth. Now there was a bird with a long tail perching on the sun, as he lay sulking just below the rim of the world, and the bird talked with the men. When the sun heard the talking he called out and asked who it was, and, out of curiosity, rose to look. And he saw the men who had come to petition him sitting on the ground, and they implored him to return and shed his light over the world. After a little while the sun spoke and said, "If you will give me a daughter of the gods to eat, then I will return and lighten the earth." The men agreed and went back to their homes, but the Bat (who always plays the part of messenger in the myths) followed them and said, "It is a daughter of men that the sun wants, not a daughter of the gods." So the men took one of their daughters and brought her to the sun as a sacrifice; and he devoured her and arose in his strength to give light and warmth to the world. But from that day death has come into the world to destroy the children of men; for, before that, they, like the gods, were immortal.

DISCUSSION.

The Chairman (Lieut.-Colonel Sir Francis Younghusband, K.C.I.E., LL.D., D.Sc.) said the paper was so packed full of information that it was rather difficult to select subjects upon which specially to speak. People in London had to remember the very difficult conditions in which the people described in the paper lived. Their environment in London was almost entirely human, whereas the environment and surroundings of the people who inhabited the Brahmaputra Valley were almost entirely of Nature. In London they lived in the midst of several millions of people amidst the handiwork of men — roads, buildings, modes of traffic, all of human agency. The Abors, on the contrary, lived amongst very few men: in fact, he doubted if any Abor saw more than two or three thousand other human beings in the whole course of his life, and his intercourse with people other than those of his particular tribe was extremely limited. On the other hand, they were incessantly in contact with Nature on a most colossal scale. They lived under the shadow of the greatest mountains in the world; they lived beside one of its biggest rivers; they were in the midst of the most beautiful forest, and apparently they had pouring down on their heads about the greatest rainfall of which he had heard — eight hundred inches in the year. He had heard that at a place called Cherrapunji there was a rainfall of six hundred inches, but he had not heard before of a spot in the world on which there was a rainfall of eight hundred inches. Living amidst Nature on that tremendous scale it was natural the people should consider that Nature was inhabited by spirits, and that they should look more to Nature for the spirits than to man. The author had said that in the main the people considered those spirits malevolent, but he also mentioned that they had a vague belief in a benevolent deity. He thought that question was worthy of careful attention on future occasions, because it would probably be found that the people did, as a matter of fact, have unconsciously at the back of their minds the belief that the benevolent spirit did in the main prevail. They seemed to have some idea of that because they sought to propitiate it, and they had some faith that their propitiations might have effect. Another point of great interest the author had mentioned was the remarkable intelligence which the people showed in certain directions. A most interesting picture had been shown of a cane bridge, which struck him with amazement, because on the Kashmir frontier he had seen bridges made of birch twigs, but he did not remember seeing one on such a big scale as that which the author had exhibited. The people, though they could not read or write and had no written language, might probably have great intelligence in other ways, and his experience among people of that kind was that they

had very retentive memories. He had also found they were very astute in the management of their own particular social and political affairs. In matters which concerned them they showed just as much intelligence as it was customary to find in more civilised peoples. The third point which particularly struck him was the author's reference to the democratic spirit amongst the people. According to the author, the chief expressed the general opinion of the people, and if he did not do so somebody else was very soon put in his place. Years ago, when he was in Chitral, at the other extreme end of the frontier from the Abor country, the chief was hereditary and was very autocratic, but he noticed it was only within certain very definite limits that he could exercise his autocracy. There were certain things he could do, but there were certain other things he could not do on any account. Apparently the slaying of the nobility was amongst the things that he could do. The chief came to him one day and said he was sorry to tell him that a certain noble had died on the previous day. Several other nobles had died quite recently, and he (the speaker) therefore remarked to him that he had noticed a rise in the rate of mortality amongst the aristocracy of the country, and it was quite likely, when he drew the attention of the Government of India to it, they would ask him to make an inquiry into the cause of the increase in the death-rate. The chief took the hint, and the nobility did not die quite so frequently afterwards. Apparently his own people raised no objection to it. One day the chief came to him and said that on the previous day, no doubt in a burst of enthusiasm and generosity, he had taken out the three hundred ladies of his household for a picnic. He said he enjoyed himself very much indeed, and so did the ladies, but he further stated that he could never do it again because it created such a ferment among his people. It would therefore be seen there were very strict limits within which autocratic rulers must keep. They could kill nobles, but not take ladies for a picnic. There were many other points to which he would like to have referred, particularly the magnificent vegetation, including the orchids, and the very beautiful insect life, but time did not permit him to do so.

Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc. (Vice-President and Chairman of the Council), said he was glad to have the opportunity of saying a few words in appreciation of the paper. It was a very great advantage to those who were condemned to stay at home doing nothing, when any gentleman, who had the opportunity of travelling in such regions as those which had been traversed by the author, had also the faculty of keen observation and of graphic description such as that possessed by Sir George Dunbar. Added to the extraordinary compactness of the paper, he admired infinitely the clearness of the pictures which had been shown on the screen. So packed with information was the paper that he thought it might very well be expanded into a book, and he sincerely trusted that in the near future the author would carry out such a work. As an old surveyor he had followed with great interest the course of explorations on the part of the Indian frontier with which the paper dealt. They owed an immense deal of their knowledge of that country to that gallant corps, the Frontier Police, to which the author belonged. The latest surveys, so far as he remembered, were completed not very long ago by Captain Morshead of the Engineers, and many of those present would remember the extraordinarily adventurous journey of Captain Bailey which finally disposed of any question as to the course of the Brahmaputra, and, incidentally, whitewashed Kinthup, the well-known explorer of the Indian Survey Department, who for a very long time had rested under a cloud of suspicion as being a somewhat romantic liar. He was glad to say that Kinthup had now come into his own. He quite agreed with the author that the people of the country probably came from the north over the mountains. At the same time it must be remembered that there was a people, who must have been very much akin to them in appearance at any rate, who once occupied the plains of the Punjab, and in days which were prehistoric were gradually driven out of the plains of India into the hills by the advancing Aryans. How far those people occupied Northern India they had no means of telling, but he believed that in the country to the north-east of Lhasa, where the beginnings of the great Rivers Salween, the Yangtse, and others, were gathered together—that sort of no man's land between Eastern Tibet and Western China—explorers and scientific inquirers would find the most interesting records and evidences of an ancient form of civilisation such as were to be found nowhere else. The people there were not savages in the same sense, for instance, that the native inhabitants of New Guinea were. There were clear evidences about them of a former state of civilisation, particularly amongst those people who, claiming independence from China, were called the Lolos and lived by themselves in sections scattered about the country. This indicated to him that it was from Central Asia that civilisation first made its start, just, indeed, as humanity first started from there. There was one point about the paper which struck him as indicating a curious feature in Nature to which he thought attention had not been sufficiently given by naturalists, and that was the curious colour-scheme which seemed to exist in Nature in regard to flowers and plants in ascending from the plains up to high altitudes. In the lower altitudes, particularly in those parts of the Himalayas where he had himself been, he had always found exceedingly bright and vivid colours. For instance, the scarlet and

deep pink rhododendrons of Simla were well known to everybody. But as one ascended higher those colours gave way to lighter shades of red, finally merging into purple, then lilac, then white, until yellow was found at the top of all. That had always struck him as curious, because he had found it not only in the Himalayas, but in the Andes, on the Hindu Kush, and on the Alps, and probably the Chairman would confirm that it was the same in other parts of the Himalayas where he (the speaker) had not penetrated. He would like to know whether there was any direct connection between altitude and colour. Another interesting point to which reference had been made was the primitive social conditions which existed where the village community was, as the author had stated, the political unit. It had been stated that the chief sometimes established himself by the strength of his own personality and of his own right arm, and if he did not succeed in pleasing the people somebody else was put in his place. He would like to know the method adopted amongst the people for replacing him by some man more popular. Did they resort to a system of voting? Was election the earliest method of selecting a chief that the world knew? And if that was so it would be a matter of exceeding interest to him to know whether primitive woman also had a vote.

Sir Charles J. Lyall, K.C.S.I., C.I.E., said that as he was totally unacquainted with the region of the Abor hills he was not able to contribute much to the discussion. He desired, however, very strongly to support the suggestion Sir Thomas Holdich had made that the paper should find its place among a series which was too little known to the outer world, but which had considerable scientific merit, the Assam Ethnological Series of Monographs. Some ten books, he thought, had already been published, each of which discussed one of the numerous races found in Assam. The author's work was of a very high order of scientific accuracy, and the paper contained an enormous mass of information; and from what had been heard that afternoon he thought the author's observations were quite capable of being put into a shape in which they would greatly interest all ethnologists. The only Abors he had seen were those who had visited Sadiya. In those days, more than twenty years ago, we had, on the whole, friendly relations with them, and our diplomatic intercourse with them chiefly took the shape of bottles of rum. They were not very frequent visitors. He had always understood that the country the author had described was one of the very wettest on the face of the globe. The adventurous journey that was taken some twenty-five years ago by Colonel Woodthorpe and Mr. Needham across from the head of the Assam Valley to the Hukong Valley proved that, while in the rest of India the weather was generally dry, in that country rain continued perpetually, and that the rainfall for that season of the year must have been very like the rainfall during the monsoon in the rest of India.

Lieut.-Colonel F. S. Terry said he understood that in 1861 the rainfall in Cherrapunji was 905 inches, the amount for one month alone (July) being 366 inches. On one occasion in that year 41 inches of rain, it was said, fell in 24 hours. He had read somewhere that the rainfall in Cherrapunji last year was 900 inches.

Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., in moving a hearty vote of thanks to the author for his most valuable paper, and expressing the thanks of the audience to Sir Francis Younghusband for so kindly taking the chair, said he had been greatly interested in the paper, because during the time he was in Assam he took immense interest in the explorations that were then carried out, such as those by Woodthorpe, Macgregor, and by Needham from Sadiya. The title of the paper was "Tribes of the Brahmaputra," but it was confined to the Abors and their congeners, and he wished some little comparison could have been made with the other tribes that were contiguous to the great river. He had been very much struck with the remark Sir Thomas Holdich had made in reference to the paper being capable of extension into a book, because he had wished for a long time that somebody would take up such a work. Forty years ago Sir Alec Mackenzie published a book giving a history of the various explorations into the country around the Brahmaputra, dealing principally with the Nagas; and Sir Charles Lyall had referred to the little monographs on individual tribes that had been published by the Assam Government from time to time which were of immense interest. If somebody would co-ordinate those into a big book, giving a history of the explorations from Pemberton downwards, it would be of extreme value. After hearing the paper he could not help comparing many of the customs of the Abors with those of the Angami Nagas. There were several points that required explanation. For instance, the wonderful skill they both showed in irrigation was striking. Then, too, what were the domesticated mithans kept for? Their milk was not drunk by the tribes, and they were kept for the purpose of ceremonial slaughter, and had also their use as a unit of pecuniary exchange. How such a custom had grown up deserved consideration. The method of cultivation known as "jhuming," which was so extraordinarily destructive, and which existed all round the frontier, in the Chittagong hill tracts, all round the Lushai country right up to the Brahmaputra,

ought to be investigated, and there were many other points of interest on which information was desirable.

SIR STEYNING W. EDGERLEY, K.C.V.O., C.I.E. (Member of Council and Chairman of the Indian Committee), seconded the motion, which was carried unanimously.

SIR GEORGE DUNBAR, who was recovering from a somewhat serious illness, was only permitted by his medical attendant to read the paper on condition that he left the room immediately he had finished. A proof of the discussion was forwarded to him, and in reply he writes:—It was a source of great regret to me that I was precluded from hearing the discussion on the paper. But I am glad to be able to avail myself of the opportunity given me to add one or two remarks on certain points brought forward by the speakers. As regards, in the first place, a belief in the existence of a benevolent deity, referred to by Sir Francis Younghusband, a number of the myths (I have collected about twenty-five in all) represent the gods as beneficent beings. Sometimes it is the Archer God, whose weapons we see in the sky (as Orion's belt); at others it is the Sun, who gave Eve to the Abor Adam. It may be of interest to add that the Abor for "human being" is *āmi*, which is not at all unlike the Arabic or Hindustani. In Lorraine's dictionary, which is based on the Padam Abor dialect, *Jimi-Jimiang* is given as "God, the All-loving," a dual and bi-sexual personality. The Padam Abors have, for a hundred years, possessed flourishing colonies along the foot hills, and within easy distance of Sadiya (the head-quarters of the frontier political district). It was to Membu that the courageous missionary, W. Krick, went in the eighteen-fifties. The American Baptist, and medical, missionaries, such as Lorraine and Jackman, have worked indefatigably among them. It is, therefore, within the bounds of possibility that the "All-loving" deity is an echo of Christian teaching; just as it struck me that the shrines of Pemakoichen bore a distinct impress of the older Nestorian missions north of the Himalayas. Still, amongst the Abors there is a general belief that the spirits of the dead medicine-men go direct to more benevolent spirits than do the souls of more ordinary mortals. And even, as regards the future state of the "laity," there exists a belief in the passing of the soul from the power of the demon who deprived it of life into the presence of a more benevolent Great Spirit. Sir Francis also referred to the intelligence of the hillmen. Now, although that sometimes doubtful advantage, the art of reading and writing, is unknown to them, they are remarkably quick at recognising themselves and their friends in photographs; understand, and occasionally scratch on the ground, rough plans to show the lie of the country, and are able to give an admirable idea of the gradients of a path—some tribes by bending up a stick, others by tearing a "section" out of a leaf. Nor is their memory contemptible. Their appreciation of the higher numbers, one hundred or over, is distinctly weak. They are strongest when the figures involved can be dealt with on the fingers and toes. Sir Thomas Holdich referred to Kinthup. I was within the borders of Pemakoichen (where he wandered, and was a slave so long) not much more than six weeks. But every step one took convinced one that Kinthup combined the indomitable pertinacity of an explorer, of which the survey of India itself, with all its records, might be proud, with, at times, the accuracy of a Baedeker. That his memory should have failed him on occasions is not to be wondered at under the circumstances. It was a source of great pleasure to those of us who went into Pemakoichen that Kinthup should have been vindicated within his own lifetime. Sir Thomas alludes to the election of the chiefs. In so democratic an assembly as the village council, if the nominal leaders wish to take a definite line in policy, such as peace or war, they are powerless in the face of definite opposition They can but persuade, which they endeavour to do in lengthy harangues. It is the "sense" of the village majority that rules. Voting would seem to take the form prevailing in the Saxon Moot—the loud shouting down of dissentients. Still, a figure-head of some kind is useful to organise "jhuming," divide the fields amongst the households, and entertain visitors. For the first he needs a clear head, for the last wealth of a patriarchal kind. So a would-be headman "nurses" his constituency by asking it to dinner. This impresses everyone with an idea of his wealth and hospitality. But, of course, as everywhere else, a commanding personality climbs irresistibly to the top of the tree. Headmen are elected by acclamation of the grown male population. There is no female suffrage, but women exercise a marked influence throughout the hills. In one Subansiri (Dafla) village I know a woman is deputed to take the annual subsidy they receive from the local government. Sir Steuart Bayley alluded in his remarks to the neighbouring tribes. I was fortunate enough to have the opportunity of either exploring, or visiting on duty, all the tribes from the Aka country to the Mishmi highlands, as well as one group of Nagas. The fullest possible notes were taken, and in some cases I lived in their houses. But ignorance of the language, indifferent interpreters, and rather short visits, do not offer firm ground for the publication of such observations as I made. But there are many obvious points of similarity in the appearance, beliefs, customs, and language of all these hill tribes. The difference between the Daflas, Hill Miris, and Galongs is very slight indeed. The Abors are distinct from the Galongs, and very different in language and customs to the Mishmis. A knowledge of Dafla would see one through the Hill Miri and Galong country, but no knowledge of Abor

would help one in the Mishmi country. Millet is the staple food amongst the wild and poor Mishmis; rice is cultivated throughout the Abor and Galong hills. Such points as I have been able to establish satisfactorily in a comparison between the neighbouring tribes have been dealt with in a Memoir of the Asiatic Society of Bengal, now in the press. There are, of course, as I should have had much pleasure in telling Sir Charles Lyall, a number of notes that are not embodied in that paper. They were collected because I had hopes, some day, of co-ordinating the whole history of the frontier in official, or semi-official, form. But I confidently expect just at present that other duties are to hand. Allusion was made by Sir Steuart to the mithan. They are the wealth of the householder and the sept to which he belongs. They are killed and eaten in sacrificial rites, and also when ratifying a treaty of peace, when they are cut up and cooked in the Tibetan bowls called *dankis*, that, with mithan, form the currency of the country. Conditions vary enormously, but a *danki*, which is a bowl of brittle white metal, ornamented with the conventional religious signs of Tibet (such as the "om," fish, wheel of life, umbrella, banner of victory, etc.), is worth from 12 to 35 rupees, according to its size, workmanship, and the ideas of the seller. Mithan are worth anything up to 90 rupees.

ELEVENTH ORDINARY MEETING.

Wednesday, February 24th, 1915; The Right Hon. Sir George Houston Reid, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Kerr, Harry Roe, care of Messrs. Steel Bros. & Co., Ltd., P.O. Box 132, Rangoon, Burma.

Nuttall, Walter Harold, F.I.C., F.C.S., The Cooper Laboratory of Economic Research, Watford, Herts.

The following candidates were balloted for and duly elected Fellows of the Society:—

Dubash, Peshoton S. G., 135, Highbury New Park, N.; and care of Postonji Bhicaji, Kimari, Karachi, India.

Lewton-Brain, L., Director of Agriculture, Kwala Lumpur, Selangor, Federated Malay States.

Mason, Charles Thomas, Sumter Electrical Company, Sumter, South Carolina, U.S.A.

Murfee, Professor Edward Hunter, A.M., LL.D., Brenau College, Gainesville, Georgia, U.S.A.

Vaishya, Ramjidas, Sweet Cottage, Gwalior, Central India.

Van Deventer, Harry R., Sumter Electrical Company, Sumter, South Carolina, U.S.A.

The paper read was—

THE ECONOMIC POSITION OF GERMANY.

By W. J. Ashley, M.A., M.Com., Ph.D.,
Professor of Commerce in the University of Birmingham.

The economic situation of Germany towards the close of last century was that of a country which had passed from being preponderatingly agricultural and had recently become at least as largely industrial, and which had left a position of internal self-sufficiency to take a place, for good and for ill, in the mutually dependent circle of international trade. It will need the recital of but a few facts to make this clear.

We may regard 1850, the middle of the century, as marking the turning-point. Up to that time the introduction of modern manufactures and machine processes had been slow; from that time onward it began to be rapid. Upon the area of the present German Empire lived, in 1850, a population of some thirty-five millions; by 1865 it had risen to forty, and in the last quinquennium the growth had been at the rate of almost 1 per cent. per year. After 1871 the movement was resumed with greater velocity; in 1900 the number of the population reached fifty-six millions, and the growth during the preceding five years had been at the remarkable rate of 1½ per cent. per year. This was the same as the highest rate ever reached by Great Britain, which was in the decade 1811–21, when the "industrial revolution" was in full swing. German writers are apt to fall into the same mistake as Malthus: to regard the growth of population as something self-moved, the independent and originating cause of all the other concomitant phenomena—the establishment of manufactures, the exchange of manufactured exports for imported food and raw materials. But it is evident that the increase of population was quite as much a result as a cause of the contemporary changes in production and transport. Of the population in 1850, three-quarters still lived upon the land; about the same proportion as in England a hundred and fifty years before. In 1871 the proportion had sunk to two-thirds; in 1900 it was certainly less than half, and of these quite a considerable proportion were largely industrialised in their circumstances and outlook. As late as 1871 there were only ten cities with more than 100,000 inhabitants; in 1895 there were twenty-eight. Going back again to 1850, Berlin then contained

less than half a million people; in 1900 it contained four times as many. It is difficult to calculate the amount of the foreign trade, in the middle of the century, of the territory that is now Germany, on account of the difference in the political organisation. It may perhaps roughly be estimated, adding together exports and imports, at somewhere about 1,000 million (one milliard) marks, or thirty marks (£1 10s.) per head of population; in 1900 it was ten times as great, or 192 marks (£9 12s.) per head. In 1850 the exports, such as they were, were half of them textiles; the larger half of these were still the older manufactures of wool and linen, which obtained all their necessary material from their own country. In 1900 the textile exports had, of course, grown enormously; but by their side, and of equal importance, were now the products of iron and steel. And finally, while long after 1850 Germany continued its old practice of exporting wheat to England, and, indeed, exported more corn and cattle to the countries outside than it imported from them down to the early seventies, in 1900 it was reckoned that between a sixth and a seventh of the nation's food came from abroad.

This will be enough to make clear the conditions on the economic side when the German Government brought forward its proposals for the creation of a big navy. It received the energetic support, by speech and pen, of many university professors, and among them of almost every economist of repute in the country. That this was so was a patent and conspicuous fact. The political opposition resented their appearance in the party arena, and dubbed them "Professors of the Fleet" (*Flottenprofessoren*). But their arguments quite certainly carried great weight with the educated classes, and especially in administrative and official circles; and they themselves were afterwards proud of the part they had taken. One of the most eloquent and widely-read among them, Professor Lamprecht—the first German historian to obtain a popularity such as Macaulay or Green or Michelet had enjoyed in other lands—after eulogising the Emperor in his History for the energy with which he set about converting the nation, adds, with emphasis, "his banner was followed, with complete understanding, before all others and from the very start, by the academic teachers of the nation."

I start by calling attention to the considerable part played by the professors, not at all by way of criticism, but simply to secure attention for their arguments; and to these we must now turn. They are most readily accessible in two volumes of Speeches and Essays, published in 1900 under the title "Handels- und Machtpolitik" ("The Politics of Trade and Power"), under the editorship, as the titlepage tells us, of Gustav Schmoller, Max Sering, and Adolph Wagner, "Professors of the Political Sciences at the University of Berlin." The conjunction of these names is significant, and especially the alliance of Professors Schmoller and Wagner, the leaders of two very different and not always very friendly schools of economists. Professor Schmoller has been for many years the most conspicuous figure among writers of the historical school, a man whose whole doctrine is evolutionary and therefore cautious, and, as some critics sometimes say, in relation to the Government inclined to temporise—a man of great influence in governmental circles. Professor Wagner, on the other hand, for an equal number of years, has pursued a course of more theoretical and abstract teaching, a course more akin to that of the still dominant English economic tradition; he is of a fiery and impulsive nature, the author of a doctrine of taxation which is sometimes found fault with as going in a Socialist direction.

Most of the arguments of the two volumes centre in the proposition, in which Schmoller and Wagner were agreed, that until Germany could protect by its own fleet its oversea trade —then, as now, some 70 per cent. of the whole —its economic position was insecure and at the mercy of any Power which could control the seas. I will quote a few passages; and in view of the language now used in Germany about the effect of sea power upon German food, I would call special attention to the references which these authoritative writers made to this particular part of the subject. They will show that the danger which Germany has incurred was contemplated as only too probable; and that they did not expect that any such doctrine as that food carried by neutrals is only conditional contraband would be of any assistance.

Listen first to Professor Schmoller:—

"However optimistically we may think of our agricultural progress, we shall remain a people which needs to import foreign foodstuffs; and therefore our existence is threatened if we are not powerful at sea."

And again:—

"The denser our population becomes, the more we must increase our exports, if only to pay for

our imports of food, materials and colonial produce."

Next turn to Professor Wagner:—

"Until we have a powerful fleet we are not sufficiently secured against the very real dangers of a hostile blockade, with all its grievous consequences for our import and export trade, for the feeding of our people and the employment of our workmen; and the position already reached and to be further gained in the future by Germany as a member of the world's economy remains entirely precarious."

When, a couple of years later, Professor Wagner threw himself on the side of the Agrarians in their movement for higher duties on corn, he carefully explained that this did not involve any change of opinion as to the purposes of a navy:—

"The naval policy is necessary for the safety of our people's food and of our workmen's employment. It is true that a strong German fleet is desirable for the sake of political power. But for our economic interests also, indeed for the security of our share in the world's trade—a share which is necessary to us and will become more necessary in the future—it cannot be dispensed with."

And on the subject of the food supply he wrote:—

"Supposing the lands which export agricultural produce are always willing and able to satisfy our demands, it must be borne in mind that, for a country in the geographical and political position of Germany, it is easier to have its supplies cut off than it would be for others. In particular, Great Britain is in a more favourable position, on account of its insular position and the supremacy which, at any rate for the time, it enjoys at sea, than our country wedged in between France and Russia."

Of the contributions by less generally known writers, two were especially devoted to the elaboration of the same thesis. One was by Dr. Ernst Francke, the able organiser of the moderate social reform movement and editor of the useful weekly journal *Soziale Praxis*. The following passage will suffice:—

"With the exception of the building trade, there is no great German industry which is not dependent to a considerable extent upon the exportation of its products across the seas . . . It is certainly not an exaggeration when we conclude that altogether some 24 to 26 millions of people in Germany" [out of a population then of 56 millions] "are dependent for their livelihood and employment upon the unimpeded inward and outward movement of commodities upon the sea routes. The keeping open of the sea and the continuance of German competition in the markets of the world is, therefore, a question of life and death for the nation, and one which concerns the labouring masses in the very highest degree."

The more detailed working-up of the argument was entrusted to a younger economist, Dr. Paul Voigt, a man of great ability too early lost to his country. Dr. Voigt produced a careful statistical survey of the whole field, which was printed first in the leading German monthly, the *Preussische Jahrbücher*, then in a separate edition soon exhausted, and then in the publication now under consideration. At the end of his survey he exclaims:—

"Almost four milliards of absolutely indispensable imports—materials, half-finished goods, and food—which, in the main, reach us by sea! What terrible misery even the temporary interruption of this importation would mean for Germany!"

And he concludes:—

"Considering how vastly the economic life of the nation is dependent on foreign trade, there can hardly be any doubt that a blockade which lasted any considerable time would bring Germany into subjection. An enemy who realises that will not allow our trade to pass by way of Antwerp or Rotterdam. He will certainly not let himself be restrained by the neutrality of weak States like Belgium and Holland, or by the thread-like fetters of international law, from attacking Germany on its most vulnerable side."

Such was the contention with which in 1898-1900 the economists of Germany came to the support of the Government's naval programme. Germany to-day, in spite of its fleet, is precisely in the position they pictured before the fleet existed. My purpose is to ask how far their account of the situation is still true? how far Germany is now vulnerable? Midway between that time and this, in 1907, one of the younger German economists, Professor von Halle, who is reputed to have been very active in organising the professorial campaign, sought to detract from the significance of its economic postulate by remarking, in a paper before the British Association, that "when a campaign was started in Germany to turn the attention of the people toward their oversea interests, they were shown to them, of course, through a magnifying glass." I cannot, myself, believe that men like Schmoller Wagner and Francke were not in earnest in every word they said; but in every political campaign there is certainly a danger of unconscious exaggeration. Moreover, it is possible that, apart from the navy, Germany is more secure to-day than it was in 1900 in consequence of being more self-contained. The argument as to the food supply might be and was used for other purposes than the support of the

naval programme; it was used by the Agrarian party in their movement for higher duties on foreign corn, as well as by those who, without being Agrarians, wished to bring about an improvement in agricultural methods.

Let us begin, then, by considering the question of food, on the assumption that outside supplies are cut off. This was the assumption, as we have seen, on which rested the argument of "the Professors of the Fleet"; and in current discussion in Germany it seems to be taken for granted that, so far, no supplies worth mentioning have actually come through. At the moment of writing (February 18th) it seems hardly likely that food will remain only conditional contraband. Even without the recent action of the German Government in taking control of all native supplies and restricting the consumption of the civilian population, it would seem to be obvious that, under present-day conditions, there is no longer any foundation in reason for the old distinction between the food of civilians and the food of the army. When the total supply is short, the more foreign food there is available for the civil population, the more native food, of course, there is set free for the armed forces. It would be absurd to suppose that the maintenance by England of the old distinction is going to be of any advantage to this country in a future war in which the enemy commands the sea: Germany in such a position of advantage would assuredly do what it has all along expected England to do now. Even if, however, no change takes place in English policy in this respect, and the difficulties Germany has to meet are only those of the scarcity of neutral shipping, the dangers and delays of transport and the expenses of payment with the exchanges against it, so far as they continue to be operative, the assumption will still hold good, that Germany will have to depend on itself.

Rye is still the chief bread grain of the people; but almost half as much wheat is also consumed; and it is customary with German writers to group the two grains together as "bread corn." And it is possible that in respect of bread corn Germany is a little more self-sufficing than it was fifteen years ago. The exact proportions will work out rather differently according to the years chosen. My own calculation, from the official figures of crop and import, is that in 1899–1900 the foreign imports were over 12 per cent. of the consumption, in 1912–13 under 11 per cent. Other estimates are even more cheerful for Germany. Professor Sering, of Berlin, perhaps the highest authority in the country on agricultural economics, thus expressed himself at a meeting of the German Council of Agriculture, in February, 1913, also, as I gather, basing himself upon official figures:—

"The magnitude of what our peasantry has recently achieved is not to be denied. With the help of co-operative societies, associations, schools and travelling lecturers, it has succeeded in lowering the proportion of bread corn which we have to draw from abroad from 16·6 per cent. in the first five years of the century to 10 per cent. in the years 1909–11. This is the work of our peasantry, for the peasantry holds in its hands more than three-quarters of the whole cultivated area of the Empire, and, roughly, the same proportion of the soil under corn crops."

And this would seem, on the face of it, to be the more encouraging for Germany, because the greater output has been obtained with the old staple, rye. According to the official returns, the annual crop of wheat rose, as I reckon, from an average of 3·8 million tons in 1899–1900 to an average of 4·5 in 1912–13, *i.e.*, some 18 per cent., while that of rye rose from 8·6 to 11·9, some 38 per cent. Germany still, before the war, imported about one-third of its wheat from America, Russia, the Argentine, and Canada; but the improvement in the yield of rye has been enough to turn it from a rye importing to a rye exporting country. In good years it now sends rye to Russia, instead of drawing it thence. In recent years it has exported, on balance, no less than half a million tons of rye annually, while in the nineties it imported, on balance, from three-quarters to a million tons.

Yet, after all, a deficiency in the total bread-corn supply of even 10 per cent.—to take the most hopeful estimate—means a shortage of more than five weeks' consumption; and I am not aware that any German economist of high standing has spoken lightly of the risk. But, outside scientific circles, there was certainly a tendency, for some time before the war, to take a very optimistic view of the situation. It was urged that, in case of need, the grain could be more completely ground, and less lost in the form of bran; and it was pointed out that, in the last resort, the quite considerable quantities of rye and wheat used for industrial purposes—for the manufacture of starch and corn brandy—could be appropriated for the miller and baker.

And in 1908 appeared an article by W. Behrendt, which attracted wide attention and had apparently a great effect on men's minds.

It was entitled "Potatoes in War," and it professed to show that any deficiencies there might still remain in the matter of bread corn could be made up from potatoes; that potatoes, as one of his admirers put it, provided "the national food reserve." For, to begin with, in the matter of potatoes Germany had more than was sufficient for itself. Next, it was reckoned that of the potato crop only 32 per cent. was used for human food, and 15 per cent. for seed, while 34 per cent. was used as fodder, 9 per cent. for the manufacture of spirits and starch, and 10 per cent. was spoilt. Surely something could be taken, if not from the cattle, from the distilleries; and, besides, the new process of potato drying and potato flake manufacture was going to save the 10 per cent. now spoilt. All that would really be necessary, then, if foreign supplies were cut off, would be a little readjustment of consumption. Accordingly the Emperor had a certain body of apparently expert opinion behind him when he declared, in February, 1913, doubtless in all confidence:—

"There is no longer any doubt that Germany not only can now, but also will be able for the future, to supply bread and meat for all her people."

A sign of the satisfaction felt in certain quarters was the article from the pen of Count Otto Moltke, a Conservative member of the Prussian Landtag and the Imperial Reichstag, which appeared in the *Preussische Jahrbücher* only five months before the war. This declared, on the authority of official figures, that the English consumption of corn was actually less than the German, so that the German harvest by itself was capable of giving the average German more than the Englishman got; while, on the same authority, it appeared that the German meat consumption had grown with extraordinary rapidity of late, and that the figures were now on a level with those of England. Just a little pinching, just a little sacrifice of comfort, was all, he implied, that war could be expected to involve.

Even accepting the data relied upon in the foregoing arguments, there were weak places in the situation which were well known to cool observers. The cessation of the import of wheat meant the withdrawal of a third of the whole wheat supply. Now wheat flour is used not only for the white rolls eaten by the well-to-do; it is mixed with rye flour in the making of all the better varieties of "black" or "rye" bread in proportions of from a fifth to a third. The increasing fondness for wheat is shown in the official statistics, which indicate a decrease in the consumption per head of rye from 151 kilogrammes in 1894–98 to some 144 in 1909–13, and an increase of wheat from 86·8 kilogrammes to 89·1 in the same period. The figures of the two grains do not quite harmonise, but they indicate the tendency in the two opposite directions. A larger resort to rye would mean a reversal of these tendencies. "A good thing," said some writers; "it is rye bread from which Germanism ('Germanenthum') has for thousands of years drawn its incomparable strength and health." But food habits are notoriously difficult things to alter suddenly.

And then the agricultural labour problem gave reason for anxiety. With the growth of the industries of Rhineland and Westphalia, agricultural labourers have been more and more drawn away in recent years from the big corn-growing estates east of the Elbe: they were attracted both by higher wages and by the hope of reaching a position of greater social independence. Let us hear Professor Sering on the consequences:—

"In the place of the labourers who have left come more and more foreigners" [the "season workers" from Russia and Russian Poland]. "According to the Occupation Census of 1907 they constituted in Silesia and Saxony 15 per cent. and 20 per cent. respectively of the male labourers. The number rises year by year. In the whole of Germany in 1912, 729,000 'legitimation cards' were issued to season workers, of whom 397,000 were employed in agriculture. More and more does the employment of these foreigners become the basis of estate management . . . So we are at the mercy of foreign Governments whether our fields shall be ploughed and reaped; and if a war should break out, the harvests in extensive districts will be ruined."

As it happened, when the war broke out many of these "Wanderarbeiter" had already reached Germany for the season; and it would seem that as many as possible have been compulsorily retained over the winter and spring. Just what is going to happen next harvest time it would be unsafe to predict; but the labour position east of the Elbe might very well create a certain sense of insecurity.

But a far weightier reason for anxiety was a fact not generally known in Germany but understood by some, at least, among the statisticians, and that was the very doubtful value of the official statistics of production. During all these months of war this has been the skeleton in the

cupboard of the German people. In all lands harvest figures are the weakest department of Government statistics. They commonly depend on estimates, not on enumeration; so that some severe critics will not honour them with the name of "statistics" at all. That the German figures contain a considerable element of probable error has been pointed out in statistical publications for some years past. Thus Professor Ballod, of Berlin, a leading statistical writer and one specially conversant with agricultural matters, wrote in 1907:—

"The method of estimating the crop was altered in 1899, and reports by local officials replaced by reports from local experts. There can be no doubt that the new method approaches more nearly to the truth; and yet even to-day errors in individual reports of as much as from 10 per cent. to 20 per cent., and in the total estimate of from 5 per cent. to 10 per cent., must be regarded as very probable."

Five years later, a writer, Georg Frohlich, in Schmoller's *Jahrbuch*—the most solid economic periodical in Germany—expressed himself in the same sense, and gave some of his reasons. The voluntary crop reporters number, he tells us, some 7,000 persons, and their districts are from 50 to 100 square kilometres in extent.

"In the time-consuming business of drawing up estimates for such wide stretches of land there are possibilities of quite considerable mistakes. Competent critics regard an average excess of from 10 to 20 per cent., or even more, as possible. Since we have had the new system of reports the figures have gone up from 12 to 19 per cent. This may have been caused by the local experts, who send in the returns and are usually very capable farmers, ascribing to other farms results as good as those they obtain themselves.

"It is possible, therefore, that our imports of bread corn are not from 12 to 20 per cent. of our consumption, but, on a moderate estimate, from 15 to 25 per cent., perhaps more; *i.e.*, that we are dependent on foreign corn for from two to three months of the year."

So far the grounds for serious doubt about the official figures have not been stated. I gather from references to publications I have been unable to obtain that Professor Ballod has become more and more convinced on the point, and has set forth the reasons in a number of technical publications. And at last the easy optimism of Count Otto Moltke, in the March number of the *Preussische Jahrbücher* already referred to, drew forth from Dr. Ballod, in the July number of the same magazine, an article which must have been disconcerting reading for those who got hold of it. The following is a summary of the argument on this, the most vital, point:—

"No one can say whether the harvest estimates are not 10 per cent., 15 per cent., or even 20 per cent. too high . . . In the province of Posen they are certainly too high. The estimated harvest, *less* what we know from transportation statistics to have been conveyed out of the province, would leave 325 kilogrammes per head, a quite impossible figure; 'even the Polish stomach does not need as much bread as that.' Higher and more improbable figures still were returned from the three other eastern provinces of Prussia—East and West Prussia and Pomerania; they would mean a consumption per head of 371 kilogrammes. Assuming a consumption in the four eastern provinces of 250 kilogrammes, which is somewhat higher than the official average for the whole empire, the harvest even then must have been, in those provinces, 22 per cent. less than the estimate."

In his subsequent argument he assumes an excess in the estimate for the whole empire of 15 per cent.

This narrative will have helped us to realise the probable state of mind of the German Government during the last six months. In spite of the much-praised efficiency of its officials, it really has not known, *with certainty*, what amount of corn it could count upon within the country. The self-satisfaction natural to all Government offices, the tendency of Agrarians to magnify their agricultural services, the wish to reassure the public, the public committal of the Emperor a year before to the big harvest figures, all these influences would naturally lead the Government to speak confidently of an adequate supply. Meanwhile there have probably been those in high places who have known that, if their armies did not "hack their way through" in a very few months, the food outlook was far from bright.

As soon as the war had been in progress a couple of months, and the official class realised that things were not going quite as quickly as they had anticipated, the Government began to be urged to use its influence and, if need be, its authority, to bring about the necessary adaptation of consumption to needs, and various attempts were made to work out the details of the necessary transposition on the basis of the official figures. One such was in a pamphlet by Von Braun, head of the Agricultural Department of Bavaria, which came out in October. He reckoned that the needs in time of war would be actually less by 3 per cent. than in time of peace, and this chiefly because the army can feed itself, to a large extent, from the resources of occupied territory, "and with the further

victorious progress of our army this will be the case in increasing measure." To allow for the same per head consumption for this diminished number in 1914-15 as took place in 1912-13, there would need to be—considering that the harvest of 1914 was already calculated as likely to be 15 per cent. less than in the record year 1913—some three million tons more bread corn than would actually be available. This could be obtained by using for bread one million tons of the barley that would otherwise be used for fodder, together with six million tons of potatoes, equivalent in food values, he states, to two million tons of bread corn, and derived from the surplus supplies of 1913 and 1914. But, as there would be already a deficit of three million tons of barley, hitherto used chiefly for fodder, owing to the cessation of Russian imports of barley, there would thus be of barley a total deficiency of four million tons. This deficit could be made up by a quarter of a million tons of barley saved from malting, because of the falling off in the export of beer and in the male consumption (with the army absent); by using the surplus supply of oats (one and a half million tons); and by turning to fodder uses the six million tons of sugar beets (equivalent to one million tons of fodder barley) set free by the disappearance of the sugar export to England. This still left one and a half million tons of barley fodder wanting. But against this could be set the surplus hay harvest of 1914, which happened to be a particularly good year and was reckoned to be as much as 11 per cent. above the decennial average. This disposed of the difficulty of ordinary fodder ("Rauhfutter"). There remained the loss of two to two and a half million tons of other imported feeding-stuffs of various kinds, maize from oversea, oilcake from Russia, and so on. But if it came to the worst, the pigs could be killed off earlier, and the nation must content itself for a year or so not to increase its stock of cattle. The bed-quilt—to use a favourite image of these writers—would be a little skimpy; but the nation would have no serious difficulty in twisting its limbs so as to keep under cover.

Some such calculations must have underlain the subsequent Government measures; and two questions suggest themselves: will the shifting around of foods and the substitution of one for another be dietetically adequate, and can it be brought about? On the first point Professor Ballod thus expressed himself last July:—

"The potato is a one-sided food. It contains carbohydrates (starchy substances), albuminoids (or protein) and fat in the proportion 170:2:1; while the need of the human body is 10:2:1. Great as are the advantages of the much-praised drying process, to prevent the loss of quantities of potatoes otherwise spoilt, it will not solve the problem; for the supplementary quantities of protein and fat have still to be supplied to fit it for human or animal use. It has been said that in time of war it would be possible to prohibit the use of corn in distilleries. But most of the corn so used is of a quality which would anyway only be used for fodder. And half the food values remains in the residues ('Schlempe') which leave the distilleries and are used for feeding cattle—indeed, almost all the most important part, the protein and fat. As these are the substances of most value—the carbohydrates can easily be supplied from sugar beets—it is doubtful whether any real saving can be effected in that manner. Far greater quantities of corn are used in the brewing of beer. But, again, we have to notice that from two-thirds to three-fourths of the protein and fat remain in the malt which is used for the feeding of cattle."

And Professor Ballod's conclusion was that, on the whole, Germany was worse off in respect of food, rather than better, than fifteen years before.

"Fifteen years ago we could hope that, if imports were cut off, we could still manage with our home supply, if energetic measures were taken, such as the prohibition of distilling and brewing; to-day that is no longer possible. True, our importation of bread corn has receded in recent years, and this explains the current optimism. But, on the other hand, we must emphasise the fact that the bread corn question cannot be considered by itself; it must be considered in conjunction with the supply of fodder and other feeding stuffs. The *total* import of foodstuffs has risen very markedly. It is a fearful self-deception to suppose Germany can live eleven months on its own bread corn. It can manage, yes; but only if it can continue to import 60 per cent. of its fodder."

The further question remains: granting that the proposed readjustment was pretty satisfactory from a dietetic point of view, as well as statistically possible, could it be brought about? It must be remembered that quite two-thirds (Sering, as we have heard, says as much as three-quarters) of the cultivated area of Germany is cultivated and mostly owned by peasants, most of them working what we should call small farms and very many quite tiny farms. To control the cattle feeding and the sales of all these small owners was a task from which even German officials might well shrink. And, within two or three months after the beginning of the war, it was found that instead of bread corn being carefully confined to human consumption, the very opposite was taking place.

In recent years half the barley, as we have seen, consumed in Germany has come from Russia, and it is this which has enabled the country to add so rapidly to its stock of pigs. When this was cut off by the war the price of barley rose even above that of rye, and the peasants naturally began to treat their pigs to rye and diminish by so much the supply available for bread.

The Government's first practical steps were to decree minimum prices of wheat and rye and bread, to give instructions as to the proportions of wheat, rye and potatoes to be mixed in flour, and to prohibit the use of bread corn for fodder. These measures seem to have met with little or no success. Dr. Helfferich, who is now in charge of German finances, boasted in a famous speech in October that the German people possessed this great advantage: "a spirit of self-sacrifice (*Opferwillen*), unattained by the French and unknown to the English." But this superiority has not displayed itself, so far, in everyday business life. And the Government was embarrassed because it could not make up its mind what line to pursue in the matter of prices: whether to make them pretty low in order to quiet the people for the time, or to make them pretty high in the hope that this would reduce consumption and prevent the national food resources from being too rapidly drawn upon. The Socialists told them with perfect truth—they can find it set forth at length in all the standard text-books of economics — that for the great mass of the people food is not a thing which will be economised to any considerable extent, save under compulsion; it is a case of what is known as "a relatively stable demand." The Government compromised, with a plan of permissible increases of corn prices at specified periods; and of course the farmers were disposed to keep back their supplies from the market till the higher prices were reached. English and German human nature is singularly alike in matters of this sort! Here in a Munich paper is a report from Mannheim, perhaps the most important corn market in the empire next to Berlin. It is dated January 14th of this year:—

"In consequence of the limitation imposed by the regulations about maximum prices, transactions, this week as last, could only be carried on on a small scale. In the produce exchange hardly any business took place, although there was no want of intending purchasers. In the retail trade a certain quantity of supply was forthcoming, although it was quite evident that farmers were holding back."

And the spirit of self-sacrifice has not hitherto been more marked among the bakers; for a fortnight later the Burgomaster of Cologne declared that in that city alone more than a hundred master bakers had rendered themselves liable to prosecution for breaches of the new regulations.

The next step accordingly was to create a great corn company, under Government auspices, with powers of compulsory purchase, which should buy up large quantities and hold them until May. But even this measure was soon realised to be inadequate. Early in January Professor Ballod published an article in *Soziale Praxis*. In this he stated, as the result of his calculations, that, in spite of all the Government's appeals to the farmers, some one and three-quarter million tons of corn had already been fed to cattle more than in the previous year. And he made the momentous declaration that, while in normal times the human consumption of corn in Germany amounted to a million tons a month, there was now available for the seven months until the next harvest only some seven-tenths (to be exact, ·714) of a million. His advice was that corn and flour stocks should be expropriated by the State. After taking a fortnight longer to think about it, the Government took his advice; and, as we all know, the people of Germany are now all being put on rations. Apparently the idea is (to judge from the restrictions imposed upon bakers) that the people must content themselves with three-quarters of their normal bread consumption, and presumably this three-quarters in weight is to contain a considerable proportion of potato flour.

And now, says the Imperial Chancellor:—

"It is a matter of organisation. The State has taken the matter in hand . . . The organisation which will have to be created will be a very difficult business, but these difficulties we expect to overcome. Our political system has shown that it can cope with the gravest tasks of organisation."

"Organisation" is a comforting word; and the German Government has in the past carried through great organising tasks. But for these it has usually taken its own time; and every student of administration knows that it has sometimes made bad mistakes. The treatment of the food problem in Germany before February 1st was certainly not particularly well-informed or strong or consistent. The appropriation of supplies by the Corn Company, the allotment to the several towns and districts, the control of the bakers and the public by

the muni ipalities, may all be managed with reasonable efficiency. But other foods, and especially meat, may have to be brought within the scope of the system; and the present plan all rests on the assumption that the people will continue to be able to *pay* for their bread. It would be most risky to prophesy; but in the best event for Germany, and assuming all imaginable docility, the nation, if foreign food supplies continue to be cut off, is going to be subjected to an irksome and discouraging *régime*.

I have left myself little time to speak of the industrial side. I shall therefore say nothing about the supplies which are most urgently needed by Germany for war purposes—copper, petroleum, and rubber. The situation as to these is pretty well understood; and I will only remark that when Germany begins to have recourse to the copper on its church spires—those undeveloped "copper mines" of which they speak so confidently the operation of stripping it off is not likely to have a very encouraging effect upon the people. What I shall say will concern a few of the staple industries. First, we must recognise that, in relation to coal, Germany stands in a very strong position. It possesses vast supplies, larger even than those of Great Britain, and it has been on this basis that its recent industrial progress has been mainly built. But the German Government, with all its skill in organisation, has not solved the problem of combining universal liability to military service with the maintenance of production. Owing to the withdrawal of its miners on military service the output of coal in what is by far the most important mining district, that of Dortmund, was 26 per cent. less in the third quarter of 1914 than for the corresponding period of the preceding year; and that for the concerns comprised in the Westphalian Coal Syndicate (which is coextensive to a large extent with the Dortmund district) was for the last quarter 29 per cent. less than the year before. Still all the workpeople the Government choose to leave at work can doubtless find employment. In the iron and steel industry the situation is almost, but not quite, as strong. Germany, in Luxemburg and Lorraine, has vast supplies of phosphoric iron ore (minette), which it has been enabled to utilise through the invention by an Englishman, Thomas, of the basic process—the second great cause of Germany's recent industrial development. The weak points are two. For the iron and steel manufactures of the Ruhr district, which produces somewhere about two-fifths of all the iron and steel of Germany, the industry has employed not only old and new iron scrap in enormous quantities together with minette from Lorraine, but also a good deal of imported ore. The proportion of imported ore to the total consumption seems to have risen lately, and in recent years to have been about one-quarter. Of this, rather less than one-third came from France, and probably even more is now available from occupied territory, but as it is minette it is not so suitable as Westphalian uses; rather more than a third came from Sweden, and some part of this is presumably available so long as Germany commands the western end of the Baltic, though the stoppage of the trade by the North Sea has already sent up its price very considerably; the other third came from Spain, and being hæmatite is now contraband and doubtless quite cut off. There must be therefore a certain limitation of raw material. This is the special weakness of the Ruhr district. That of the Lorraine-Luxemburg district is in the matter of labour. It has no old stock of iron-workers, and it is largely dependent on season workers, who come from Italy. These usually go home for the winter; and Germany is said to be negotiating now with Italy to get them back.

We should expect that the large demands which the German Government are making upon the manufacturers of munitions of war would have kept the iron and steel concerns very busy. Yet if we may rely on the usual trade returns, the total pig-iron production of the German Empire has been less than half, from August to December, of what it was in the previous year; while the deliveries of the steel syndicate in the fourth quarter of 1914 were not much more than half what they had been in the corresponding period.

Such iron-workers as have been allowed to remain are probably busily employed on Government orders; and the same process of adaptation of engineering and other works to the requirements of war time that has been so conspicuous in England has been equally successful for the time in Germany. But another side of the economic problem is presented when we reflect that machinery and iron and steel products head the list of German exports; in 1913 they furnished over one-fifth of the whole volume of export trade. Most of this trade must have been lost since the war began. Some

40 per cent. of Germany's total export trade used to be with the now hostile countries, and probably quite this proportion held good for the iron and machinery group; the removal from the seas of Germany's shipping, and the very limited tonnage available of neutral shipping, can have left very little of the remainder. This fact has a very direct bearing on the question, how Germany is going to pay for any imports it may manage to get hold of, and helps to explain why the Government is hoarding gold.

While the allied mining, iron, and engineering groups form the solidest part of the German industrial structure under present circumstances, the second of the export groups, the textile trades, forms the most vulnerable, and that both on the side of the supply of material and on the side of the disposal of product. They contribute about 12 per cent. of the total value of German exports, and give employment to some 1,370,000 persons. Of these the large majority are females; the figures, therefore, do not represent the same number of dependents as in the heavy male trades. On the other hand, the numbers dependent on employment cannot be reduced by military service; nor can the textile trades, except in the case of woollen goods, be much helped by Government orders.

The consumption of cotton wool has been rapidly growing. To go no further back than the time of the first naval programme, in 1896-1900 it averaged 302,000 tons; in 1911-1913 it averaged 475,000. This the country has in recent years obtained, to the extent of some 17 per cent. from Egypt and British India, and these sources of supply are now cut off; to the extent of 79 per cent. from the United States; and the rest from miscellaneous sources. It is well known that German spinners carry much larger stocks of cotton than their English competitors, and, to judge from the statistics of the International Federation, the stocks of cotton in German spinners' hands on March 1st, 1914--the so-called "invisible supply"—was enough for approximately twelve weeks' normal consumption. Supposing, like some other trades in Germany, the cotton-mills are now working half-time, that allows for twenty-four weeks. Spinners' stocks in August are commonly considerably lower than in March, and this fact may balance the probability that there were considerable quantities stored in the commodious warehouses of Bremen. Allowing for the probability that large quantities were seized at Antwerp, and making allowance for the great depression in the trade in August and September, when a quarter of all the textile operatives were totally out of work, it is difficult to see how the German cotton-mills can go on for more than, say, nine months from the outbreak of the war without fresh supplies. These considerations sufficiently explain the growing anxiety of late about American imports. Considering, moreover, how limited is the available neutral shipping, there can be little doubt that Germany will have to pay heavily for all the raw material it can get.

The German cotton manufacture, however, is a typical example of an export industry in that it is dependent on export for a very large part of its market — far more than are the iron and machinery trades. It is not so dependent on an outside market as Lancashire is, yet probably between a third and a half of the fabrics produced are sold to foreigners. Some of its branches, we are told, such as mixed fabrics and hosiery, are dependent on foreign markets for half their sales, some even for three-quarters. A glance at the complicated trade figures will show that somewhere about half, perhaps more, of all these exports has hitherto gone to what are now hostile countries. Even supposing — a large assumption — that Germany could manage to reach its neutral customers, the price it would have to pay for its material would put it at a hopeless disadvantage in all the countries that could be supplied from England, America, or Japan.

So far as the supply of material is concerned, the German woollen industry is in a worse case. With the improvement in German agricultural methods, the number of sheep kept in the country has been rapidly dwindling. In 1900 it was nearly ten millions, in 1912 it was under six millions; for comparison it may be added that in England and Wales alone in that year it was over eighteen millions. The woollen industry is, therefore, almost as dependent on imported material as the cotton trade. Three-fifths of the mill consumption were merino. Of this more than four-fifths have hitherto come from Australia and the Cape; and of the crossbred (the other two-fifths consumed) almost half usually comes from Australia also. Altogether, two-thirds of the raw material have been brought from what are now hostile countries. The Argentine and Uruguay, the only other large sources of supply, can doubtless increase largely their sales to

Germany; but it cannot be supposed that they can do anything like fill up the gap.

As to stocks in the country, the foremost trade authority in this country reported, at the end of 1918, that stocks both of raw wool and tops were then "abnormally low everywhere." The one cheerful bit of news for Germany has been the appropriation by the Government of quantities of wool found in Roubaix and other French woollen centres now occupied by its troops. But the amount can hardly be enough to keep the industry going for any length of time. It will have been noticed in the papers that the military authorities have taken over all the woollen blankets and the like to be found in the Berlin factories and shops; and that a wool week has recently been organised to give patriotic persons an opportunity to contribute all the old woollen articles they can spare for the manufacture for the benefit of the troops of what may be called without any disrespect by its trade name of "shoddy."

As to the silk industry, that can be pretty comfortable about its materials so long as Italy remains neutral. But hitherto half its product has been exported; and of these exports more than a quarter, *i.e.*, an eighth of the whole, before the war, came to England. Of particular classes of fabrics the proportion exported to England has usually been much larger. Thus, according to the last figures I have been able to get hold of, of the silk and velvet trade of Crefeld—those for 1907—15·5 per cent. of Crefeld output went to England and 6·6 per cent. to France—*i.e.*, in all between a fifth and a fourth.

Of the smaller textile industries, those of linen and hemp, and that of jute, I need only add that of the former four-fifths of the material have hitherto come from abroad and more than three-quarters from Russia; and of the latter practically all the material has been drawn, until the war, from British India.

From textiles one naturally turns to the leather trades. But I have only time to remark that about half the total supply of hides was drawn from abroad, and about a third of the import came from enemy countries, chiefly British India and Russia. There is already such a shortage of leather that the Federation of German Boot Manufacturers represented to the Government in the middle of January that, unless something were done to overcome the leather famine, many boot manufacturers would have to close down in a few weeks.

Of other industries I may just mention the chinaware and porcelain group, usually disposing of two-thirds of its output abroad, and recently sending a third of this export to what are now enemy countries; and the jewellers and workers in precious metal who normally export some three-quarters of their product.

These are all among the older trades of the country. But if one turns to the newer trades the result is the same: they are all cut off either from a large part of their market or from a large part or the whole of their material. Take three very different examples. The shipping business of Germany has of late years been growing by leaps and bounds; and a system for supplying, and incidentally for controlling, dock labour at Hamburg has been exhibited for our admiration. But now that the German merchantmen are mostly shut up in port, the labour exchange in the month of November, 1914, found engagements for only 2,300 dockers, as compared with 33,000 in the same month of 1913. Aniline dyes, again, have been one of the main boasts of modern Germany: in the years between 1900 and 1913 the value of the exports almost doubled (from 77 to 142 million marks), and of these a third used to go to Great Britain and other enemy countries. And, finally, take that humble but popular commodity, margarine. For its production Germany imported palm-nuts and copra in 1913 to the astounding value of 226 million marks, six times as much as in 1900. But of the palm nuts—about half the whole—nine-tenths came from British West Africa, and of the copra almost half from other British possessions.

Bearing in mind the conditions I have sketched, let us place side by side two remarkable utterances. One is from Prince von Bülow in his book "Imperial Germany," published a year or so before the war:—

"We have entrusted millions to the ocean, and with these millions the weal and woe of many of our countrymen. If we had not in good time provided protection for these national possessions we should have been exposed to the danger of having one day to look on defencelessly while we were deprived of them. But then we could not have returned to the comfortable economic and political existence of a purely inland State. We should have been placed in the position of being unable to employ and support a considerable number of our millions of inhabitants at home. The result would have been an economic crisis which might easily attain the proportions of a national catastrophe."

Compare with this the language of Dr. Rathenau, head of the great Allgemeine Elektricitäts-Gesellschaft, in December last:—

"German industry is faced with the task of converting its organisation, hitherto based upon a system of imports and exports, into an organisation appropriate to a country thrown upon its own resources."

And this, he implied, there was no doubt it would be able satisfactorily to accomplish.

Which of these prophets is most likely to be justified by the event? Is it possible for an industrial and exporting State to retrace its steps, without undergoing great hardship while it adapts itself to its narrower quarters? It is not only the food quilt that the nation has to twist its limbs to get under; it is the employment blanket also. Von Bülow, no doubt, was unconsciously magnifying the need for a navy, just as Rathenau has been minimising the difficulties of adaptation. But can it be seriously doubted that the balance of probability lies with the ex-Chancellor? We need not expect any dramatic breakdown of the whole economic structure; for some months the country may struggle along on its present supplies, and it will probably continue to get in some of its materials from abroad and pay for them by exports or by gold. Moreover, the vast Government orders will keep large bodies of the people employed, and enable them to purchase their requirements, even at enhanced prices. But I cannot but believe that, after a few months, if the Allies continue to command the seas, unemployment and short time will become more and more prevalent, and pauperism and distress grow to alarming proportions.

In spite of the activity of the war material trades, and the vast numbers called up for military service, the proportion of the members of trade unions totally unemployed—of short time there are no figures—was more than three times (7·2 per cent.) as great at the end of last December as the average for the preceding five years, and almost three times as great as in England. And while military orders were continuing to reduce the total percentage, it is significant that the number went up again in December among the building operatives, the textile workers, the leather workers (other than saddlers), the porcelain workers, the bakers, miscellaneous factory operatives, and even among municipal employees.

We are told of the wonderful organising and administrative ability of the German civil service. I am inclined to think that there is a tendency in some quarters in England—in reaction from extravagant anticipations of an early victory for the Allies—to go to an opposite extreme and overestimate the effectiveness of the German too official machine. The German *Beamtenthum* has done considerable things for its country—it is honest, hardworking, systematic. But I decline to take it quite at its face value. It makes a proud and justifiable display of all its achievements, but I doubt if it can show anything quite so big as the way in which this country took up the colossal task, not only of sickness insurance, but also of unemployed insurance—which German administrators had been afraid to tackle—and all in a single year. And the social situation in Germany is such as to add vastly to the task. It simply is inaccurate to say, as Dr. Helfferich did, in his historic speech, that "Germany has at its disposal an incomparably better economic organisation than its enemies," if he meant England. Our whole system of adjusting wages in the staple trades of the country by negotiation between masters and men, imperfect as it is, is the admiration and despair of social reformers in Germany. Here it works with friction, of course; but, as we have had the satisfaction of seeing of late in the coal industry, and in the railway service, it is working; and in Germany in the big industries there is nothing like it. No one who knows Germany at all intimately is ignorant of the fact that the relations between classes in this country — much as they leave to desire—are incomparably more friendly, more intimate, and more wholesome. With all our faults, we are essentially a far more united people. This cannot but tell in a struggle like the present. And when the German administrators have to take up in earnest the task of "return to a purely inland State," and of the redistribution of the working people among the occupations that survive, they will find it, I expect, one beyond their powers.

DISCUSSION.

MR. ALFRED MILNES said he had listened to the paper with that kind of admiration which those who knew the reputation of Professor Ashley had experienced, with every satisfaction, but with not the slightest surprise. It had occurred to him (the speaker) that there was just one small contribution which quite pure economics might make to a paper of such extreme concrete weight as the Professor's, and that was a little caution to follow-

citizens to remember that what was called economic pressure would always have to be reckoned, not only in terms of commodities and their sufficiency or insufficiency of supply, but still more importantly in terms of the psychological conditions which that deficiency might arouse in the people concerned. There were, as he (the speaker) had ventured to put it in rather a frivolous way, wide extremes with which men would meet what was called economic pressure. There was the class of man who would say, "Oh, look here, my half-a-crown pair of gloves has cost me two-and-nine. Really, we cannot stand this kind of thing and the war must stop." There was another set of people who would say, "The enemy has got my coat and waistcoat, and I will be hanged if they shall not have my shirt, but I am not going to give in." There was a whole difference between the effects that might be produced by a different quantity of pressure upon people of different psychological habit. It was the great Austrian school, led by Professor Bohm-Bawerk, that had brought forward more conspicuously perhaps than any other thinkers that psychological aspect of the matter. There seemed to be a danger on the part of fellow-citizens of perhaps slightly exaggerating the hopes that were built upon what was called economic pressure upon Germany. We had learnt to discount the German culture, and to think much less of their civilisation during the last few months, and some of our leading scientists had at last dared to say that there was to be found some scientific attainment outside of Germany after all; but we should not be in the danger of underrating what he believed to be one of the great Teutonic characteristics—their dogged endurance in a struggle. If that were so, it had to be remembered that that economic pressure, so brilliantly described in the paper, had to be estimated in two dimensions—firstly, in its quantity reckoned commoditatively, and, secondly, in its effect reckoned psychologically.

The Chairman (the Right Hon. Sir George Houston Reid, G.C.M.G., D.C.L., K.C.), in moving a vote of thanks to the author for his valuable paper, said the fact that no lively discussion had been excited by the paper was one of the strongest compliments that could be paid to the Professor. He (the speaker) had had a long experience in the art of picking holes in speeches and addresses, but he could not manage to find any serious objection to any of the statements contained in the paper—which was one scarcely to be dealt with in an impromptu fashion, it being so full of solid elements of thought. One of the most striking features of the address was its absolutely impartial and well-balanced statements; the author had discarded patriotic feeling and indignation in dealing with the subject because it was one in which such elements would tend to weaken and confuse the value of the paper. The war had upset almost all the moral attributes of everyone in judging of anyone who happened to be on the other side. It was almost a consolation to know that our German antagonists had acted so badly that we could honestly criticise their conduct, although it was not quite a natural characteristic of the British race to express hatred, even under circumstances of great provocation. He admired the balance of the British race under the tremendous struggle in which it was engaged. He did not know that we had fully realised what a tremendous strain it was going to be upon the Empire and upon our Allies before it was over. The Germans had an enormous number of good qualities; and now that they had thrown overboard the Ten Commandments, they had, for the moment, acquired additional strength, which, however, had in it the elements of future weakness. In one of the quotations contained in the paper would be seen the sort of view, before the war, which had been expressed in the actions of the German Government since the war. Dr. Voight had said, sixteen years ago: "there can hardly be any doubt that a blockade which lasted any considerable time would bring Germany into subjection. An enemy who realises that will not allow our trade to pass by way of Antwerp or Rotterdam. He will certainly not let himself be restrained by the neutrality of weak States like Belgium and Holland, or by the thread-like fetters of international law, from attacking Germany on its most vulnerable side." That was a remarkable expression, coming, as it did, from a distinguished German in a time of profound peace. Evidently at that time there was the idea that even International law was a fetter, and only a fetter with the strength of a thread. That was the worst thing about Germany in the present dreadful struggle—she had broken down laws which even barbarous tribes centuries ago honourably respected. Just compare such dreadful outrages upon law and honour as Germany committed every day with the behaviour of a noble race in New Zealand, the Maoris. The Maoris had desperate fights with British regiments, and showed the greatest heroism and bravery before they were subdued. They used to send word to the British soldiers when they were going to attack them! Now German culture had degraded Germany below the savage level, because the Germans knew well the crimes against all law and all humanity of which they were guilty; and the fact that they were brave, the fact that they were strong, and the fact that they were enlightened would only cover them with greater infamy in the years to come when future generations pronounced upon the war. This great nation of ours was never engaged in a more bloody struggle, but she was never engaged in a struggle which, to all mankind and for centuries to come, would bring greater glory upon her name; and in the victory which must come we might hope to see the energies and talents of mankind, not engaged in a bloody struggle to occupy some place in the sun, but to fill those large and unoccupied places in the glorious suns of human enterprise, human skill, and human love.

The vote of thanks was carried with acclamation.

The Author, in reply, said although he had tried to keep feeling out of the paper, in the background of his mind he had some very sad thoughts indeed. He owed more than he could say to Germany, and he hoped he would never be ungrateful for what he had learnt from his German teachers. But during recent years he had felt more and more alarm when he had gone to Germany to see the constant nervous tension in which people seemed to live, their inability to realise the great things which were being done in the world, and the great thoughts which were being spread in the world outside Germany. There seemed to be a self-centred strain, a self-satisfaction, and a readiness to take offence; and now the breach was to him unspeakably painful. It was for that reason he thought it better to keep all sentiment as far as possible out of the paper.

THE HARDWOODS OF PANAMA.

The cacique is a small tree growing about 45 feet high and a foot thick, in scattered clumps or thickets on the hills. It is comparatively rare, and the timber is generally considered the most valuable in the country, being durable, hard, impervious to insects, and very beautiful. The ground colour of the wood, when cut and aged, is a rich deep red, with black spots and stripes. The natives demand at least about 20*s*. for a cacique whipstock or cane, and such canes have been sold in New York for as much as £5, according to a recent report by the Sanitary Inspector of the Isthmian Canal Commission. There are probably about 100,000 trees of timber size in the country, and the value of the timber, aside from the cost of getting it out, would be about £1,400,000. The name of this tree is derived from the fact that the ancient Indian chiefs (caciques) used the wood for their sceptres, or batons of office. The ground wood is used by the natives as a styptic. There are three kinds of trees, referred to in common Central American usage, as "caoba;" all three occur in the higher parts of Panama. The first two, Guarea caoba and Carapa guianensis, attain a height of 100 feet or more. Their timber is so similar to Honduras mahogany, that it is equally valuable—about £18 per 1,000 feet. The Guarea caoba will run from 3,000 feet to 5,000 feet per acre, and the amount now standing in the country is valued at £36,000,000. The Espave, often 5 feet thick at the base, grows to a height of 80 feet to 120 feet, of which 40 feet from the base is clear. Some of the large branches are available for lumber. Some forests average fifteen large trees to the acre. The leaves are large, somewhat heart-shaped, light green, and very abundant. The Espave is prized so much by the natives as a shade tree, that they usually spare it in clearing for planting. They use the timber, however, for their canoes, many of which last for a generation or more. The wood is of a reddish bay colour, resembling mahogany, for which it is often mistaken. It is close grained, durable, and uniform in texture, and works readily. There are probably 1,500,000 of these trees in Panama. The timber is worth £16 per 1,000 feet, and the total value is about £26,000,000. The quayacan is somewhat smaller than most hardwoods, averaging 70 feet high and 2 feet thick, and branching 80 feet from the ground. The leaves are small and compound, and the greyish-black bark is rough and shaggy, with longitudinal furrows. The inflorescence is a mass of magnificent golden blossoms. The wood, hardest and most durable of the timbers of Panama, is akin to the lignum-vitæ of the West Indies. Railway ties of the quayacan have been in use on the Panama Railway for many years. It is so hard that holes had to be bored for the spikes. There are probably 1,000,000 of these trees in Panama, worth about £3,000,000. The laurel, 3 feet in diameter, grows on hillsides to a height of 100 feet. The bark is white. The wood is yellow, hard, fine grained, durable, and easily worked. There are probably more than 1,000,000 laurel trees in Panama, with an average yield of 1,000 feet per tree, and a total value of £12,000,000. The Santa Maria, or calapa, is a large evergreen, attaining a height of 100 feet or more, with more than 50 feet clear, and with a diameter at the base of about 3 feet. The bark is comparatively thin, mottled grey and black, and slightly rough. It peels from the wood readily. The wood is greyish white, as hard and elastic as hickory, and also similar to teak. It is durable, straight, and close-grained, takes a good polish, and splits longitudinally better than most tropical hardwoods. It was used by the Indians for bows, and is employed almost exclusively for palanquin poles. There is probably £14,000,000 worth of this timber in Panama.

SELF-BURNING LIMESTONE IN SYRIA.

In the district of Hauran, a volcanic district of Syria, south of Damascus, east of the Upper Jordan, a curious stone is found which might be described as a "self-burning limestone." At this place the rock lies in a stratum between ordinary limestone; it is of a greyish-black colour, and when freshly broken it has an odour of petroleum. The quarrying, according to the American Deputy-Consul at Jerusalem, who has lately visited the district, is easily done with primitive picks and other tools, as the rock is quite soft and full of seams. The stone is broken into small pieces with hammers and piled up against the bank of rock. A wall of the same material about two feet high is roughly laid up round the pile on three sides, making a pile of small stones eight to ten feet long, and nearly as wide, and two feet at the front, rising to nearly three times that height at the back where it lies against the bank. In building the wall around the pile small holes are left in which to start the fire.

When the kiln is ready to burn, a few small bunches of straw are placed in the holes mentioned, lit with a flint and steel, and in a short time the whole pile has ignited. The men then begin working on a new kiln while the other burns and cools. After about twelve hours of burning the stone has all become converted into lime, except the stones in the wall and the very top layer which are only about half burned. When cool the lime is air-slacked and sifted, to remove any pieces not thoroughly burned, which are thrown into a new pile to be fired again. The lime is white and said to make a very strong plaster, superior to the ordinary lime burned with brush, but sells at a much lower figure, because of the low cost of production.

COCOA-BEAN COATING IN TRINIDAD.

The practice of claying cocoa beans began in Trinidad about twenty years ago, and soon became prevalent throughout the island. It is now practised generally by the large estate owners, and is regarded as the best method of preserving the bean. When the cocoa bean is first taken from the pod it is enveloped in a thick white layer of tissue, and this tissue in the process of fermentation becomes shrunken, discoloured, and slimy. The former custom was to wash the slimy covering from the bean before drying, but this entailed much labour and reduced the weight of the bean. It also hastened the drying process, often to the injury of the kernel. It is also contended that washing renders the integument of the bean more brittle and liable to crack, in which event the bean would take up foreign scents and lose its own aroma. The clay wash was considered the best means of preserving the cocoa beans. The process is simple and rather primitive. According to the American Consul in Trinidad, the fermented beans, after being partially dried, are piled on the drying platforms, and pulverised earth, ferruginous and devoid of organic matter, is sifted over them. About one pound of earth is used to every one hundred pounds of wet cocoa beans. The beans are thoroughly stirred with wooden shovels and the earth adheres to the mucilaginous matter clinging to the integuments.

The beans are then spread out on the platform to dry in the sun. When drying is nearly completed they are piled in heaps and sprinkled with water until the whole mass becomes sticky. Then the labourers perform the so-called "dancing" act, by trampling the beans with their naked feet till the seed coats assume a glossy appearance, when they are again spread out in the sun until sufficiently dry. The object in claying the bean is to render it impervious to moisture, to prevent decay and to preserve the aroma of the kernel. Moisture encourages the growth of mould, which imparts an unpleasant flavour to the kernels and depreciates their market value. Abuses have crept into the process of claying, resulting in excessive claying in order to increase the weight of the beans. Instead of the average clay wash, one pound to one pound and a half of clay to one hundred pounds of wet cocoa beans, unscrupulous dealers have of late years been introducing as much as six to ten pounds of clay to the hundredweight.

It is said that the beans in their natural state will not take more than one pound and a half of clay to the hundredweight, but by the addition of glue and other foreign ingredients the coating of the beans will consume from six to ten pounds. Another object of claying, in addition to preserving the beans, is to render them uniform in colour, as a higher price is obtained when the beans do not vary in colour. All cocoa handled by jobbers and country dealers is sold to merchants of the city, and the latter, appreciating that the remedy rests with them, have recently refused to buy excessively clayey cocoa. This course has had its effect in reducing the quantity offered. The Agricultural Society of Trinidad, the Chamber of Commerce, and the Cocoa Planters' Association, realising the injury that may be done to the cocoa industry in Trinidad by the abuse of claying cocoa, have recently made a joint effort towards ending the practice, and have caused posters to be placed in public places in the city and in country districts giving warning that "if excessive claying be not discontinued, it will be necessary in the general interest of the colony to bring the matter to the notice of the Government, with a view to the introduction of legislation making excessive claying a punishable offence."

VEGETABLE IVORY EXPORTS FROM ECUADOR.

Increased purchases of vegetable ivory nuts for manufacture into buttons are being made from Ecuador. Take the United States, for example. Imports into that country during the year 1908 amounted to over 14,000,000 lbs.; in 1912 to 23,000,000 lbs.; and in 1913 to 29,000,000 lbs. These imports were nearly all derived from Colombia and Ecuador, the latter country alone furnishing nearly 17,000,000 lbs. in 1913. Tagua, the vegetable ivory nut, is the seed of the fruit of a species of palm tree (*Phytelephas macrocarpa*), which grows plentifully in the western or tropical region of Ecuador, Colombia, and the interior of Brazil. Queensland produces a similar but larger nut with a hole through its centre. The producing ports of Ecuador, in the order of their importance, for unshelled nuts are, according to the United States Consul at Guayaquil—Esmeraldas, Manglaralto, Bahia, Manta Cayo, Puerto Bolivar, Macara, Machalilla, and Guayaquil; for shelled nuts—Manta Guayaquil, Cayo, Machalilla, Manta, Esmeraldas, Macara, and Puerto Bolivar. The tagua obtained in Puerto Bolivar and Macara, the largest in size and highest in price, is brought to Guayaquil for export. Owing to political disturbances in the country, recent data could only

be obtained from the Province of Manavi and the vicinity of Guayaquil. From the first-mentioned district reports state that during the year 1913 there were received in the port of Bahia about 8,000,000 lbs. of tagua, of which quantity 4,755,100 lbs. were exported shelled, leaving about 3,244,000 lbs. of shells and discarded nuts to be thrown into the sea or used for fuel.

The percentage of defective nuts is difficult to estimate, since it depends entirely upon whether they have been picked from the palm or gathered from around it. Ripe nuts that have fallen to the ground are likely to be worm-eaten, especially if left for any length of time, whilst those picked from the trees are usually sound. A prominent exporter of Guayaquil states that worm-eaten nuts are not brought to that market, because exporters refuse to buy them. The defective nuts are separated at the haciendas and thrown into the river before the tagua is sent to Guayaquil, where any worm-eaten nuts found are removed, for otherwise the entire shipment is liable to become infected. About 250 tons thus disposed of at Guayaquil annually could, it is said, be purchased at a very low price, although the export duty amounts to about 5*s*. 6*d*. per 100 lbs. on shelled and about 3*s*. 4*d*. per 100 lbs. on unshelled tagua. Recent prices at which tagua was sold from the warehouses were about 14*s*. per 100 lbs. for the extra large tagua from Macara and Puerto Bolivar, for ordinary commercial nuts 12*s*. per 100 lbs., rejected nuts being offered by one exporter at 2*s*. per 100 lbs. To the above prices must be added the export duty and shipping expenses. There is at present in the Province of Manavi but one shelling machine in operation; in other parts of the Republic there are several. It has been stated that a former United States Minister to Ecuador has organised an industrial company with all the capital subscribed. The officials are to be in Manta, where a plant will be installed, the object of which is to square the nuts ready for cutting into buttons, etc., by removing all superfluous corners and parts, and then export the improved article. By so doing the freight expenses will be materially reduced, allowing a larger percentage of profit on the exported material.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Enemies' Goods—The patterns of Austrian and German cloths collected by the Board of Trade, and placed on public exhibition successively in London and Manchester, have attracted incomparably more attention than had the articles been placed on the market in the usual way, and probably more than their real importance warranted. Patently, the bulk of the exhibits came from the collection of a single merchant firm, whose name they bore, and these were amplified by indiscriminate contributions from other sources. Technically, the samples were not more educative than such as might be turned out of the pattern cupboards of many a shipping merchant in this country and not more representative. The exhibits afforded no serviceable index to the full range of fabrics produced in the two countries, and could not be held to represent even the main articles of production. The general absence of prices detracted from the utility of the display—an omission the more serious because price was in most cases the only material point at issue. Where prices were given no date was attached, and although the samples were undated the internal evidence of fashion seems to attribute them to a period not less than one or more than four years' distant. These considerable blemishes did not of course obliterate all interest, and in Manchester it was observable that visitors' examination of the articles was conscientious if brief.

Some Continental Cottons.—Specimens were shown of fancy cottons ornamented with mercerised stripes, and also of artificial silks. The production of similar goods employs some thousands of looms in the Bradford area, and in few cases could the duplication of the pattern involve any appreciable difficulty. Exception may be made of the warp-figured artificial silks, of which the production is too tedious to afford satisfactory wages to weavers who can get other work. It is perhaps not surprising that the cotton poplins shown in the exhibition should be perceptibly inferior to those manufactured here. A series of cotton trouserings in imitation of what the tailors call cashmere cannot be denied the merit of plausibility. The imitation is superficially excellent, the printed dots of aluminium powder simulate a woven silk stripe admirably, and the duplex printing of back and face are skilfully calculated to deceive. Granting that the wearer thoroughly understands that the goods are made to look at and not to wear, that their fine features will disappear in an absurdly short time and their smartness melt promptly into the shabbiness of rags, the articles may be approved of unstintedly. It is of some interest to note that the process of aluminium printing by which they are decorated was developed originally by a firm of Leeds lithographers and its use extended to English calico printers at large, by whom many million yards of cottons have been printed for more defensible uses than as trouserings. The absence of prices on these goods leaves it impracticable to make comparison with some not less handsome cotton and shoddy mixtures which are made in Yorkshire, and are a hundred times less likely to disappoint the customer. The more brilliantly finished cottons are distinct from the comparatively spineless tweeds and trouserings made from cotton waste, and obtainable, according to the tickets upon them, at some 5-10*d*. a yard. There is hardly a doubt that such cloths could be made here were it seriously worth the while of manufacturers. It may be thirty years since woollen tweed makers in the Colne Valley tried and abandoned the trade

in all-cotton goods, and there is the minimum of reason for questioning their choice. As recently as twenty years ago better imitations of worsted were made in all-cotton by various English makers whose interest led them into other fields. The truth is that the contentment of the consumer is not separable from the interest of the manufacturer. Long experience shows that the cloths which gave satisfaction in use are those for which the consumer comes back, and it is incontrovertible that for a certain range of purposes wool, even in its most debased forms, holds advantages denied to cotton.

Specimen Woollens.—The fortuitous character of the official collection is emphasised in many odd ways. "Spanish stripes," which were cloths of some moment in the days of the East India Company, engage nowadays only such interest as may attach to the sale of 4,000 to 5,000 pieces a year to Shanghai, with driblets possibly to the South American market. The goods are plain-woven woollen scarlets, embellished at the end of the piece by three successive strips of highly coloured piled mohair and a scroll of stitched lettering. The stitched addendum "Made in Germany" may have explained a prominence unwarrantable upon the ground of commercial importance. The inclusion of a handful of samples of union felts by no means overrates the strength of the Austrian felt industry, upon which British slipper-makers, for example, have depended so largely for supplies. Coals are carried to Newcastle with a vengeance when German patterns of crossbred wool dress serges are exhibited in England. The comment of an English woollen manufacturer upon a heap of cotton-warp meltons, inferior to those of Leeds, tweeds shabby in comparison with Colne Valley goods, heavy woollens of the Batley type, and of low-grade boiled-finish woollen goods, was at all events unflattering. The results attained in those classes afford nothing for English woollen manufacturers to copy, and if the general rule holds good in their case the products offer no advantage in price.

Upholstery Fabrics.—A disproportionately large place in the exhibition occupied by upholstery goods adds little to the knowledge that might have been gained at any time within a few years past by shop-window gazing at home. It is, however, instructive to know from one of the most eminent sellers of upholstery that not all the cloths hitherto imported from Germany have been of German manufacture. The stoppage of supplies during the war has singled out some of these quasi-German goods as French. Canvas printed or tamboured in new art designs from the Wiener Werkstatte is German enough in style to escape suspicion of French origin. Turkey towelling printed in broad stripes of black and grey with a white floral figure appeared in the exhibition as a furnishing fabric under a Lubeck trade-mark. It is possible that the sense of colour rather than the instinct for cleanliness is consulted in the jacquard figuring of towels intended for the toilet. The taste for terra-cotta and green striped towels, for heliotrope flowered and checked towels and for some similar floridities, more probably grew up on the Continent than in England. The export division of Manchester trade could doubtless match the brilliancy of certain orange, purple, green, and black calico prints, or the undistinguished common prints in which the supreme matter is one of price.

Typical German Goods.—Naturally, the exhibits included a variety of soft flannelettes labelled "eider reversible," and so on. The goods are not strange to English eyes, but those in the best position to commence their manufacture here evince no inclination to do so, and the reason lies elsewhere than in the want of capital or ability. Attempts which do not begin at the beginning with a certain blend of raw materials and a special method of spinning have hitherto failed, as they presumably always must fail, to duplicate this article. Hosiery may conceivably form the subject of a later exhibition to itself, although German hosiery developments are tolerably well known already to English traders. Some stockinette fabric was shown in Manchester, and in one specimen a net of cotton remained as the foundation with the wool existing as a furry fluff above and below it. A glove fabric exhibited was of the more interest for being shown in conjunction with the Bolton yarn from which it has been hitherto made in Germany.

Contrary Twists.—The direction, left-hand or right-hand, in which yarn is twisted, has effects larger than are always realised. As the direction of the twist controls the angle of the refraction of light it becomes possible to divide light and shade upon the plane surface of table-linens, where the fleeting play of light has given cause to sometimes fruitless speculations. Twist plays its part in increasing or diminishing the tendency of cloths to shrink after wetting and in promoting the durability of clothes. Contrary twists in stranded yarn bind and hold each other together. Attention to twists and some other details effects the crimping of a fabric, and the production consequently of a crape. As may be readily demonstrated, an extremely hard twisting in one direction sets up a strain contorting the whole thread and inducing it to fold upon itself. The feature last named has been availed of in making elastic surgical bandages without rubber, threads of hard right twist alternating in due rotation with threads of left twist, so that in a fabric of very open structure the interstices are taken up by the contortion. It may appear odd that so elementary a matter can form the subject of an apparently valid patent to use which English firms are contesting. The patent is that of a German, Teufel, and the applications in respect of it are made apparently more with a view to the weaving of elastic puttees than of bandages. The

applications seem to be the only ones made in connection with a purely textile matter since the opening of the war.

Kapok Fibre.—It has been reported for some years that extensive use has been made by the German naval authorities of the fibre kapok. The filaments are unicellular without the natural twist which befits cotton for spinners' purposes, and the fibre has been used mainly for stuffings. "Golden down" is the upholsterers' euphemism for cleaned kapok, and the feature that has disqualified it for spinning into thread has made its fortune as a filling for cushions. Kapok does not mat or felt in the same way as the recognised fibres for spinning. Reports of success attained in spinning kapok have come to hand periodically from different parts of the earth, and somewhat pointless reports in view of the fact that it pays to adulterate kapok with cotton, and that adulteration is too frequently undertaken. *Eriodendron anfractuosum* is its botanical name, and it is imported from Java and neighbouring countries. The virtue of kapok, from the naval point of view, is a buoyancy which is calculated to be many times greater than that of cork. Hence comes the use of the fibre in numerous life-saving waistcoats now offered for sale. Kapok is understood to be used upon German ships as a stuffing for lifebuoys and mattresses, and, except that it may be more inflammable than certain available alternative stuffings, there is nothing convincing to be said against its use for similar purposes in English practice.

CORRESPONDENCE.

THE DECORATIVE TEXTILE INDUSTRIES AND THE DESIGNER'S RELATION THERETO.

I was present at the meeting on the 17th inst., and heard Mr. Wilcock's paper, but the hour was already late, and I did not feel justified in prolonging the discussion.

It seemed to me that the author of the paper was hardly right in saying that the designer's name always remains unknown to the public. It is true that a large proportion of the purchasing public are indifferent in the matter, and do not know much about the characteristics of this or that artist's designs; but hundreds of designs in textiles have been sold with the artist's name appended as a recommendation.

Where the artist's work shows personality and independence, or some definite characteristic, his name becomes known and his designs inquired for —as in the case of William Morris, Lewis Day, Walter Crane; or, in the past, A. W. Pugin, W. Burges, Dr. C. Dresser, and many others, whose work, good or bad, was distinctive. On the other hand, the authors of designs which are merely variations, however excellent and useful, of what has been done before, but do not possess any personal quality, do not acquire personal recognition. They do not possess the quality which induces special notice in the purchasing public. The designer's name has often sold a material very unfitted for its immediate purpose, simply because the purchaser thinks that anything by that artist must be right. Even with pictures, many are bought on the strength of the painter's name rather than for intrinsic merit.

I certainly think that it is essential for a designer to understand the details of the manufacture of the material for which he is designing. He will otherwise put the manufacturer to needless expense, or find his designs unacceptable.

Especially is this a primary need in the case of designing for machine production, where the risks of loss are so serious. It is only with a correct knowledge of what the machine can or cannot do profitably that the designer of the finished material can do it or himself justice.

It is futile to exclaim against machinery. If the designer is a real artist, and knows the working of the machine, and *where its limitations lie*, he can produce that which will charm.

J. D. CRACE.

The aim of the Schools of Art is to provide a sound basis for all branches of Art. On this foundation the teaching of design is carried on. Much of the time of the students is taken up in learning to see accurately, in training the hand, and in studying objects of recognised Art value. This is the basis of all Art work, and that this fact is recognised is shown by the number of students sent to the schools by manufacturers and the design studios. Students are trained for all branches of Art, and specialisation is only possible at a later stage. On this foundation the teaching of design is carried on in the accepted paths and in the traditional styles. To teach the latest novelty and fashion of the moment would be to court disaster. The student would have nothing to fall back upon, and the design would be out of date before he was able to make any commercial use of it. No doubt those who run studios would be glad to have a fresh supply of students on "tap," well up in the latest craze. What would become of them afterwards? No teacher can prevent the immature student from taking round his designs and trying to get a start. Those who supply textile manufacturers with sketch designs at £1 each probably make more money than they would in a design studio. There is no difficulty with the present organisation of the schools in training the designers for textile industries. The need is for more studios to which they can go. In Paris there are a larger number than in London, with the result that the designer can change from one to another with more certainty of employment.

Regarding the Art masters, Mr. Wilcock complains that they are mostly men who have been unable to

make a mark with painting and have drifted into teaching. This is emphatically not the case, and if he will study the conditions of appointment and qualifications insisted upon by the Board of Education he will find that the training is a lengthy and comprehensive one, and must commence at a fairly early age. The 200 Art Schools in the kingdom are in charge of men highly trained for their particular work, with skilled assistants for various subjects, and it will usually be found that the design classes are in the hands of practical designers teaching part-time only: for instance, one school in London has two masters on the staff who are principally designers of textiles, and a third who occasionally does textile design. These three have recently sold designs to German firms.

Mr. Wilcock does not mention the number of designs done in his studio for abroad, but makes a point of the foreign designs bought by British manufacturers. To capture foreign trade it is necessary either to prepare the design specially for the market, purchase the design in the country for which the manufacture is intended, or make the design and manufacture of such excellence that it is beyond competition. The Arts and Crafts Society, by its exhibits abroad, has done much to popularise British designs. Designs for printed linens, chintzes, cretonnes and wallpapers were shown at their last exhibition. Mr. John Sanderson remarks that "Continental people, who were a little out of the common and desired something really nice, always used English wallpapers, and the same thing applies to the United States." Is none of the credit for this due to the Art Schools?

The statement of Mr. Wilcock that Germany has been supplying our great Wallpaper Combine with more than one-third of its annual demand for design is misleading. The Combine produces most of its designs in its own studios. It is one-third of those purchased, in addition to this, that comes from Germany.

In an address at Macclesfield, in 1909, Mr. Frank Warner speaks of the "real practical training the students receive now-a-days in Macclesfield, Manchester, and the leading Continental technical schools." Again, in 1912, speaking of the National Competition of Schools of Art, he says: "By its influence and attitude, always gentle and never dictatorial, it has promoted industrial Art training in this country in such a way that in a land which only a few years ago was almost barren of Art, we now have so much that is good and promising that, much as we may yet have to learn, we are not only no longer ashamed to meet the world in competition but, I believe, with the exception of France, there is no country which can excel or even equal us in artistic manufacture."

No doubt much remains to be done, but the schools are really working to give the students a good training so as to help the manufacturer, and no good will come from lecturers who imagine that the schools are not progressing with the times, and simply abuse them and the Art master. I will conclude by again quoting Mr. Warner:—

"Surely the obvious way successfully to meet such competition is to discover, through our technical schools, the most economical methods of manufacture, and through our Art Schools to impress upon our goods the best taste in form, design and colour. But this can only be accomplished if the manufacturers wake up to a true appreciation of the value of the work which is being done in some of the schools, and could be done in all of them, and therefore take advantage of the benefits which the community, aided by the State, has provided. It is true, as I have already pointed out, that the value of these benefits is sometimes leavened by the absence of the practical element in the teaching; but, in spite of that, the manufacturers would, with but rare exceptions, profit by employing the products of the Art Schools rather than those of their own training."

CHAS. A. EVA, A.R.C.A., Lond.

In support of Mr. Arthur Wilcock's remarks on the subject of the effective employment of the Art students from our Government and municipal schools, and the wisdom of bringing them into closer touch with trade, I should like to say that in 1837 our State School was founded at Somerset House with the definite purpose of encouraging the study of Art in relation to industry and manufacture, and even since then the Education Department, we are told, has endeavoured, in fits and starts, to advance this branch of work. We cannot, however, boast of much success. It is deplorable that a nation like ours should have allowed its natural instincts for the beautiful to lie fallow, and our industrial performances in this direction to go unco-ordinated and untrained, when we have gone ahead in so many other ways that contribute less to the amelioration and sweetening of daily life. There is no doubt that we owe something to Schools of Art; but what industry requires is men practised in design and its adaptation; it has little or no use for craftsmen who are too proud of their creations to carry out any design but their own, or to adapt themselves to the necessities of industrial production. The schools have failed to meet the requirements of industry in the important branch of Art teaching in practical conditions, which is the one that most affects the prosperity of the country. It is true that manufacturers have looked in vain to them for practical designers; broadly speaking, there is a lack of sympathy between the schools and the manufacturers: one has an artistic standard of its own, and apparently refuses to consider in a logical manner the calls of the other. Our trading competitors abroad have been very active, and, if we ever hope to advance as they have done, the application of Art to industry must be fostered with far greater energy than in the past.

W. G. PAULSON TOWNSEND.

OBITUARY.

Sir Charles Augustus Hartley, K.C.M.G., M.Inst.C.E.—Sir Charles Hartley died on the 20th inst. at the great age of ninety, for he was born in 1825. For many years he was the leading authority on matters connected with river engineering. In 1867 he reported on the River Scheldt, and in the same year he obtained a prize offered by the Emperor of Russia for plans for the enlargement of the port of Odessa. He advised on the improvement of the Mississippi; on the route for the Panama Canal; on the navigation of the Hooghly; the harbour of Madras; the port of Trieste; the Nile barrage; the improvement of the Don and the Dnieper, and many other rivers, including indeed the Thames. From 1856 to 1907 he was Engineer-in-Chief and Consulting Engineer to the European Commission of the Danube, and it was in the improvement of the Danube navigation that his principal reputation was gained. He was also, from 1884 to 1907, a member of the International Technical Commission of the Suez Canal. He was the recipient of numerous foreign orders awarded for his services as an engineer, and was the author of various important books on his own special subject.

Sir Charles was awarded the Society's Albert Medal in 1903 in recognition of his services in the improvement of river navigation, and in the same year he became a member of the Society. In the following year he was elected a Vice-President, and he held this office for three years. He was knighted in 1862, and made a K.C.M.G. in 1884.

James Spicer.—Mr. James Spicer died at Eltham, Kent, on the 22nd inst., in his seventieth year. He was the eldest son of Mr. James Spicer, senior, wholesale stationer, and, in common with his brother, Sir Albert Spicer, Bt., M.P., he assisted his father in founding the well-known firm of Messrs. James Spicer & Sons, Ltd., wholesale stationers, paper warehousemen, and paper manufacturers. In addition to his business activities he took a deep interest in a number of charitable institutions.

Mr. Spicer was elected a Fellow of the Royal Society of Arts last year.

GENERAL NOTES.

The Trade of Gambia.—Gambia is the smallest British colony in West Africa, lying on either side of the Gambia River between French Senegal and Portuguese Guinea, with an area of about 3,619 square miles. The principal industries are the cultivation of ground nuts, and, in the far interior, cattle-breeding. The present conditions as a result of the war will affect the prosperity of Gambia less than the other colonies or protectorates farther south on the coast, as the colony's products go principally to France and England. The increased volume of trade and shipping in 1913 over previous years is due to the influx of new French firms and the consequent competition in trade. The United Kingdom continued to furnish the greater amount of cotton goods and hardware, followed by France and Germany in the order of their importance. Rice came principally from Germany, France and Great Britain, Germany leading. Germany also furnished the greater amount of spirits (gin), followed by the United Kingdom and France respectively. France supplied the greater amount of sugar, followed by the United Kingdom and Germany respectively. Salt, all refined, was furnished by the Portuguese colonies. Tobacco, principally unmanufactured, was practically all furnished by the United States, and wine by France.

Indian Trade and the War.—A Press *communiqué*, issued in India, states that Mr. M. M. S. Gubbay, I.C.S., Collector of Customs, Bombay (on leave), has, as an experimental measure, been attached for a few months on special duty as Indian Trade Commissioner to the Board of Trade City Office, 30, Cheapside, London. In this capacity he will assist in finding outlets in the United Kingdom for Indian exports of raw and manufactured articles which in normal years go to Germany and Austria-Hungary, or to other parts of the Continent, and which have lost their market owing to the war.

Eau de Cologne, a French Product.—"La Chambre Syndicale de la Parfumerie Française" has expressed the opinion that the title "Eau de Cologne," by which this popular perfume has been known for more than two hundred years, should not be altered. It is essentially a French product, even if "made in Germany." It is composed of ingredients produced in France, bears a French name, and is manufactured by a process perfected in France.

The "Côte d'Azur" at the San Francisco Exhibition.—Notwithstanding the war, and the fact that many of the principal hotels have been turned into hospitals filled with wounded, the hotel industry on the French Riviera will be well represented at the San Francisco Exhibition. The pavilion of the "Côte d'Azur" will occupy more than half the space allotted in this department to France. Upward of five hundred of the principal hotels on this coast will be represented. The various sections will embrace every subject connected with hotel administration, from architecture to sport, golf and tennis included. The principal beauty spots, the varied attractions and places of historical interest will be well illustrated by magnificent collections of photographs. The fine panorama representing Monaco and Monte

Carlo, as viewed from the sea, which figured at the Paris Exhibition in 1900, will also be shown, together with dioramic views of Nice and Mentone. These exhibits have just been shipped, *viâ* the Panama Canal, by the "Jason" of the United States Navy.

"DEFENDERS OF THE EMPIRE."—Messrs. Raphael Tuck have forwarded for review a packet of their postcard reproduction of Mr. H. Payne's picture of representative units of our land and sea forces. The brilliant and familiar uniforms of old, reproduced in their actual colours, are naturally adopted by the artist in preference to the monotonous, if serviceable, khaki, and the result is a bright and attractive picture. The types include the Royal Horse Artillery, Royal Field Artillery, Household Cavalry, Lancers, Hussars, Foot Guards, Highlanders, Infantry of the Line, Yeomanry, Territorials, Sikh Infantry, Bengal Lancers, N.S.W. Lancers, New Zealand Mounted Rifles, Royal Canadian Infantry, South African Rifles, Marines, and Boy Scouts. In the background we have a "Dreadnought," cruisers, destroyers, submarines, and torpedo-boats, while in the air are shown an airship, a hydroplane, and a monoplane. The profits of the sale are to be devoted to the Prince of Wales' National Relief Fund.

COMMERCIAL MUSEUM IN TENERIFFE. — The Superior School of Commerce, an official institution of Teneriffe, is installing a commercial museum, having the character of a permanent exhibition of products of various countries. Merchants and manufacturers are invited to send samples of their wares or products, accompanied by such information as to prices, freights, etc., as it may be convenient to give. The school offers to reimburse exhibitors for the cost of sending samples. Practically all the young men of Teneriffe destined to commercial careers take a course in this institution, and it is expected that a creditable exhibition of foreign products constantly before the eyes of the merchants of the Canary Islands will be of great benefit to their trade. It may be added that the Canary Islands are highly prosperous, and that in them there is some demand for almost every article entering into modern commerce, except such as are suitable only to cold countries.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock (except where otherwise announced):—

MARCH 3, at 4.30 p.m. — WILLIAM POEL, "Shakespeare's Profession." SIR SQUIRE BANCROFT will preside.

MARCH 10.—J. W. GORDON, K.C., "Patent Law Reform and the War." DUGALD CLERK, D.Sc., F.R.S., will preside.

MARCH 17. — H. M. THORNTON, "The Industrial Uses of Coal Gas." SIR CORBETT WOODALL, D.Sc., M.Inst.C.E., Governor of the Gas Light and Coke Company, will preside.

MARCH 24, at 4.30 p.m.—LADY LUGARD, "The Work of the War Refugees' Committee." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, will preside.

APRIL 14. — T. THORNE BAKER, "The Industrial Uses of Radium."

INDIAN SECTION.

Thursday afternoons:—

MARCH 18, at 4.30 p.m. — LIEUT.-COLONEL A. C. YATE, I.A. (retired), "The Indian Army." The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., will preside.

APRIL 15, at 5 p.m. — PERCEVAL LANDON, "Basra and the Shatt-ul-Arab." The RIGHT HON. EARL CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., will preside.

MAY 13, at 4.30 p.m.—M. M. S. GUBBAY, I.C.S., "Indian Trade and the War."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MARCH 2.—DAVID LINDSAY (Leader of the Elder Scientific Exploration Expedition), "The Northern Territory of Australia: Past, Present, and Future." The RIGHT HON. SIR GEORGE HOUSTON REID, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, will preside.

MAY 4.—S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced:—

FRANK BAINES, M.V.O., Principal Architect in charge of Royal Palaces, "The Restoration of Westminster Hall."

E. W. HULME, "Patent Law."

ROGER FRY, "Post Impressionism in Design."

C. H. SHERRILL, "Ancient Stained Glass."

A. S. E. ACKERMANN, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

AUGUSTUS VERNON HARCOURT, D.C.L., LL.D., D.Sc., F.R.S., "On an Economical and Smokeless Grate, and on the Measurement of the Efficiency of Open Grates."

ALDRED LECTURE.

Thursday afternoon, at 4.30 o'clock:—

MARCH 11.—M. PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "L'évolution de l'école Belge de Peinture (1830–1900)."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

M. H. BAILLIE SCOTT, "House Building—Past and Present." Three Lectures.

March 15, 22, 29.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

FOTHERGILL LECTURES.

Monday evening, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, F.I.C., F.C.S., "Motor Fuel." Three Lectures.

Syllabus.

LECTURE III.—MARCH 1.—"*Cracked*" *Spirits.* The effect of degree of temperature used—The use of water or steam—Surface action and its supposed effect—Processes in use—The utilisation of gases in solution to increase vapour tension—The steam engine *versus* the internal-combustion engine for motor traction—Conclusions.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Fothergill Lecture.) Professor Vivian B. Lewes, "Motor Fuel." (Lecture III.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Professor A. Fowler, "The Spectra of Stars and Nebulæ."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Lieutenant R. W. A. Brewer, "Running Costs of Motor Vehicles."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. Discussion on Mr. J. J. Eastick's resolution "That in the opinion of this Meeting representing the London Section of the Society of Chemical Industry, the Council of the Society should petition the Government to take such steps as will tend to the permanent production and refining within the Empire of Sugar sufficient for the Empire's consumption."

Electrical Engineers, Institution of (Local Section), Mining Institute, Newcastle, 7.30 p.m. Mr. C. P. Sparks, "Electricity applied to Mining."

TUESDAY, MARCH 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. D. Lindsay, "The Northern Territory of Australia: Past, Present and Future."

Japan Society, 20, Hanover-square, W., 8.30 p.m. Mr. W. Gowland, The Metals and Metalwork of Old Japan."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. J. Pope, "Colour Photography—Scientific Applications: Photographic Appreciation of Colour in Monochrome." (Lecture I.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Mr. N. S. Done, "Some Common(-)Places."

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. J. Curle, (*a*) "The Production of Samian Ware and its Development"; (*b*) "A Note on a Visor Helmet from Nijmegen, Holland."

Rontgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. Mr. A. Fleck, "The Chemistry of the Radio Elements."

WEDNESDAY, MARCH 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. W. Poel, "Shakespeare's Profession."

Civil Engineers of Ireland, Institution of, 35, Dawson-street, Dublin, 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. S. W. Bridge, "The Soluble Chlorides and total Chlorine in some English Cokes." 2. Mr H. Hawley, "The Routine Detection and Estimation of Boric Acid in Butter." 3. Mr. T. E. Wallis, "The Structure of Pepper—some new features." 4. Mr. A. de Waele, "The Occurrence of Chlorine in Coal."

Electrical Engineers, Institution of (Students' Section) Victoria-embankment, W.C., 7.45 p.m. Discussion on "The Applications of Electrical Engineering to Warfare." 1. Mr. P. R. Coursey, "Communication, Wireless, etc." 2. Mr. S. G. Killingback, "Laying and Firing Mines." 3 Mr. E. L. M. Emtage, "Searchlights and Projectors." (Local Section.) The University, Birmingham, 7.30 p.m. Mr. C. P. Sparks, "Electricity applied to Mining."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. G. C. Druce, "The Sciapus and other Abnormal Human Forms in English Church Carvings."

THURSDAY, MARCH 4...Geographical Society, Kensington-gore, W., 5 p.m. Professor J. W. Gregory, "Suess's Classification of the Eurasian Mountains."

Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Messrs. J. A. Wheldon and W. G. Travis, "The Lichens of South Lancashire." 2. Mr. A. W. Hill, "The Germination of *Marah* (*Echinocystis Marah*, Cogn.)." 3. Dr. Marie Stopes, "New Types of Stem-anatomy in *Cycadeoidea*, and a well-petrified new species." 4. Mr. W. E. Collinge, "Description of a new Genus and Species of Terrestrial Isopoda from British Guiana."

Chemical Society, Burlington House, W., 8 30 p.m. 1. Messrs. O. C. M. Davis and F. W. Rixon, "Steric influence. Static and dynamic." (Part II.) 2. Mr. P. C. Rây, "Interaction of dimercuriammonium nitrite and the alkyl iodidesnascent mercurous nitrite." 3. Mr. H. D. Dakin, "The constitution of allantoin and allied substances."

Royal Institution, Albemarle-street, W., 3 p.m. Sir H. Warren, "Poetry and War." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. G. H. Rodman, "On Pollens, and the Fertilisation of Flowers."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. R. G. Keevill, "Some Notes on Wind Pressures."

FRIDAY, MARCH 5...Royal Institution, Albemarle-street, W., 9 p.m. Professor E. B. Poulton, "Mimicry and Butterflies."

Geologists' Association, University College, W.C., 8 p.m.

SATURDAY, MARCH 6...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Recent Researches on Atoms and Ions," (Lecture III.)

Journal of the Royal Society of Arts.

No. 3,250. VOL. LXIII.

FRIDAY, MARCH 5, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 10th, 8 p.m. (Ordinary Meeting.) J. W. GORDON, K.C., "Patent Law Reform and the War." DUGALD CLERK, D.Sc., F.R.S., will preside.

THURSDAY, MARCH 11th, 4.30 p.m. (Aldred Lecture.) M. PAUL LAMBOTTE, Directeur des Beaux Arts au Ministère des Sciences et des Arts de Belgique, "L'évolution de l'école Belge de Peinture (1830–1900)." LORD SANDERSON, G.C.B., K.C.M.G., Vice-President of the Society, will preside.

The lecture will be delivered in French.

Further particulars of the Society's meetings will be found at the end of this number.

FOTHERGILL LECTURES.

On Monday evening, March 1st, PROFESSOR VIVIAN B. LEWES, F.I.C., delivered the third and final lecture of his course on "Motor Fuel."

On the motion of the Chairman, LIEUT.-COLONEL ALLAN J. C. CUNNINGHAM, a vote of thanks was accorded to Professor Lewes for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, March 2nd; The RIGHT HON. SIR GEORGE HOUSTON REID, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, in the chair. A paper on "The Northern Territory of Australia: Past, Present, and Future," was read by Mr. DAVID LINDSAY (Leader of the Elder Scientific Expedition).

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

TWELFTH ORDINARY MEETING.

Wednesday, March 3rd, 1915; SIR SQUIRE BANCROFT in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Misra, Gadadhar Prasad, 193/2, Harrison-road, Calcutta, India.

Park, Kendall, 50 Calle Ballester, San Gervasio, Barcelona, Spain.

The following candidates were balloted for and duly elected Fellows of the Society:—

Horn, Wilbur F., M.A., Carlisle, Pennsylvania, U.S.A.

Mayeda, T., Shimboricho, Shiba, Tokyo, Japan.

Myers, Fred L., Kensington-place, North-street, Kingston, Jamaica, British West Indies.

Salur, Raja of, Fort Salur, Vizagapatam District, Madras, India.

The paper read was—

SHAKESPEARE'S PROFESSION.

By WILLIAM POEL.

It is with some diffidence that I ask those assembled here this afternoon, who have spared a little time in days of stress and strain, to consider with me, in the name of Shakespeare and in the interests of the profession to which he belonged, the present condition of the English theatre. The apathy of Englishmen towards the art of the drama is due to the conviction that in the matter of amusement the public is supplied with what it wants, and that what it gets is the best of its kind. This, however, is as illogical an argument as it would be to say that every smoker gets the tobacco he most appreciates, even if he can afford to buy the best in the market. The fact that Government legislation became necessary in order to prohibit the adulteration of food, suggests that customers

do not always receive, in return for their money, an article bearing a genuine label. It is within the memory of most of us that, in the poorer districts of London, for many years margarine was sold under the name of "fresh country butter." Perhaps, too, shopmen trifle with their customers to a lesser extent than those who provide entertainments. What, for instance, can be more misleading than the following paragraph, which surely was inspired by a theatrical manager and found its way into the newspaper, more in the manager's interest than in that of the public: "The —— Theatre, as a popular priced house playing *the highest class attractions*, is meeting with *convincing* success. Last week Mr. Brandon Thomas and company, in 'Charley's Aunt,' played to huge audiences." Long ago, Schiller pointed out that the public must not be blamed for the quality of the drama which is presented before it, for he wrote:—

"The assertion so commonly made that the public degrades Art is not well founded. It is the artist that brings the public to the level of his own conceptions; and in every age in which Art has gone to decay it has fallen through its professors. The people need feeling alone, and feeling they possess. They take their station before the curtain with an unvoiced longing, with a multifarious capacity. They bring with them an aptitude for what is highest, they derive the greatest pleasure from what is judicious and true; and having these powers of appreciation, if they have once tasted what is excellent, they cannot be satisfied with inferior productions."

Nor do I stand alone in claiming the right to challenge the continuance of the present state of affairs with regard to our theatres. Frederic Harrison, the historian and critic, has said on the public platform: "I do not know what blight has fallen on the English theatre that the public will not look at anything really tragic. No manager would to-day accept either 'Lear' or 'Othello' if it were a new work by an unknown man." More recently Mr. John Palmer, the dramatic critic of the *Saturday Review*, has said: "The theatre has no real connection with life. It cannot even be said to be a mirror before the public face, as that face appears in its least exalted and exacting moments. Rather it has contrived a monstrous caricature of the public face, which the public has been induced to recognise as its own in the absence of anything in the nature of a portrait." It would be easy to go on quoting criticisms of a similar character; but I would rather point to the fact that it is not only the theatre on which a blight has fallen, for Mr. Thomas Beecham, in a letter written to the *Daily Chronicle* a few days ago, refers to the future development of music and says: "Little will here avail but a complete mental right-about-face on the part of the public and player alike; nor do I think this the time for soothing words. To-day we have an opportunity for reconstructive activity, such as is never likely to come our way again; but before the rebuilder makes his appearance the critic and iconoclast must plead measure of licence . . . and, for the life of me, I cannot see why a man, whenever nowadays he decides on telling the truth, should at once be accused of following in the wake of Mr. Bernard Shaw."

It is in the spirit of these words that I ask for your indulgence, while I endeavour, to the best of my limited ability, to indicate how, in my opinion, commercialism to-day has injured Shakespeare's profession.

To begin with, if I am to succeed in persuading you that when we visit the theatres we do not get proper value for our money, I must first explain what I mean by proper value. In the autumn of 1913 I travelled over the Continent, with the object of making some personal acquaintance with the theatres abroad, and my tour extended from Amsterdam to Vienna, *viâ* Berlin, and then through Munich to Paris. I had made a similar tour some twenty years previously, and need scarcely say that I found in my second visit some improvements to admire and some things to regret.

The German stage in 1913 had no great actors—a shortcoming which, perhaps, was not peculiar to that country. If it could be said that acting generally had improved, then the loss to the stage of those pre-eminent in their calling might have passed unnoticed. But there was then in Germany no company of actors of marked reputation; none, for instance, to approach in all-round talent that of the once celebrated Saxe-Meiningen troupe. As different reasons are put forward by way of explanation, it is worth while, in the interests of dramatic art, to examine them.

Some thirty years ago national theatres maintained a certain standard of acting which perhaps found the fullest recognition at the Théâtre Français. Nor had this standard altogether disappeared. In 1913 we still found it in Amsterdam, in Vienna, and at Petrograd—as, for instance, in the acting of that great artist M. Chaliapine. Then at the municipal theatre in Amsterdam actors still sustained their traditions, and the picture background did not wrest the attention from the figures in the play. The artists showed restraint, and had complete

control over the methods by which they expressed their art. With them it was not enough for an actor to be natural or to appear to be natural, but to be able to create various types of living men and women who did not resemble each other in speech, in action, temperament, or capacity.

In Vienna the Burgtheater and the Volkstheater in 1913 retained a supremacy for style which was especially evident in the art of stage management, and which had a distinction and finish not to be found in the German theatres. The spontaneity with which the action was sustained was remarkable, while the supernumeraries were moved and grouped with admirable judgment and skill. At the Volkstheater comedy was acted with an apparent ease which gave additional charm to its vivacity and humour. Nature, probability, and good taste were never overreached, while the actors showed more than ordinary observation and inventive faculty. These Viennese artists, besides, were particularly successful in creating "atmosphere": for whether the environment was the palace, the monastery, or the office, the characters gave the impression of being born and bred in their surroundings. Thus every play had its vivid portraiture. Even a dull play, in the hands of these excellent actors, ceased to appear dull, for it was always fresh in interesting detail, in colour, and in movement.

Notwithstanding the excellent acting at Vienna and Amsterdam, it must not be inferred that in 1913 Germany was behind Austria or Holland in its achievements on the stage, but the public of Berlin and Dresden was drawn to the theatre with other intentions than to enjoy the art of the actor. At Leipsic it was said that Reinhardtism—if it is pardonable to invent such a word—had made good acting no longer possible. If there were any truth in a statement which was obviously exaggerated, it meant that public interest, for the moment, was more centred on the art of the producer than on that of the actor. It is not an uncommon notion that shortage of good actors is occasionally inevitable. Even admitting that actors are born and not made, still, when exceptional talent is not wanted on the stage, it is not likely to find its way there. To give an instance, Dr. Gerhart Hauptmann's new staging of Schiller's play "Wilhelm Tell," at the Art Theatre in Berlin, was, in its setting, perhaps, the finest achievement ever seen on the stage. The walls of the theatre disappeared, and the spectator was confronted with the mists and the mysteries of the mountains. But scenic illusion of this kind has one serious drawback—it leaves little place for the actor's art. In sight of the wonderful panorama which confronted the spectator, it was no longer necessary to present Schiller's play through the words of the poet or with the help of the actor. To take another instance, Professor Reinhardt's reputation is deservedly great as a producer, and every new staging for which he is responsible arouses interest throughout the whole of Germany. This does not mean that Reinhardt cares only about staging. He is himself too sound an actor to overlook the importance of the actor's art; but his methods do not tend to raise the standard of acting. The perfect balance maintained between the acting and the staging of "The Living Corpse," in Reinhardt's production of Tolstoy's play, was noteworthy, and Signor Moissi's acting of the part of "Fedja" was both effective and moving. Yet the performance generally was more an illustration of clever realism than one of creative art.

Most theatres in Germany in 1913 were experimenting with backgrounds, sometimes using curtains and the apron platform, when Shakespeare's plays were given, and for other plays building the most elaborate settings on the revolving stage. Meanwhile, actors complained that their theatres were being turned into huge mechanical boxes, which provide the producer with every possible contrivance for getting "atmosphere" on to the stage or a quick change of scene, and yet in reality these contrivances only separated the actor more and more from his audience and from the natural conditions under which his art thrived. Now and then, in these new-fangled theatres, an artist who had more than ordinary mastery over his speech and his gesture would capture for a few moments the undivided attention of the audience; then background, lighting, and stage, as if by magic, vanished from the spectator's mind because the audience was under the sway of the poet's words and the actor's emotions. Stage illusion, said the elder Coquelin, was essentially the actor's, and not the painter's, business. With the help of the author's words he should conjure a living scene, a mental picture of moving ideas, which must be as vividly realised by the spectator as by the speaker, and which must stand out from the background as a thing apart from it.

There can be no doubt that German actors had been for some time in a nervous and restless mood, and realised that they were working under strained and artificial conditions.

Since Court and municipal theatres have had to compete with private theatres the standard of art had been lowered. At the Royal Opera Houses "Madame Butterfly" and "La Tosca" have been added to the play-bill, and at the Court theatres mere scenic plays or patriotic farces were often given, where the actor was hampered in the use of his art by the wooden figures he impersonated. On the other hand, the Art theatres were interested in methods of production of a Gordon Craig kind, or in dramas by the most modern poets; while the people's theatres perhaps secured the best repertory of plays and the cleverest actors. At the same time, it must not be inferred that Germany in recent years has been losing ground in her determination to maintain theatres which should be homes of Art. In this respect in 1913 she easily stood first, with France, perhaps, no longer a competitor; while the American and English theatres were still in the grip of financiers who took no interest in the drama as an art.

I will now give you a list of the plays that I saw during my brief stay in a German town not much larger than Manchester. Hamburg, which may be said to include Altona, the adjacent town, has a population of just over one million. It has several well-managed theatres, but the bill of fare that counts in drama may be said to be provided at four playhouses, although the Schiller Theatre, where I saw acted "Wallenstein's Camp" and "The Piccolomini," would in its class rank with our own Lyceum in its present days. The town Opera House and the town Altona Theatre were under one direction, and had a subvention to the extent that they did not pay any rent or any charges for water or gas. The Hamburg "German Playhouse," a very large theatre, and "The Thalia," a smaller one, received no subvention, and were expected to pay a small interest on the capital subscribed by some rich men of the town, whose object was to secure for themselves and their following more elasticity in the choice of plays and in the method of their presentation than could be possible at the Opera House and Altona Theatre.

I arrived in Hamburg on a Sunday afternoon, and I remained in the town eight days; and, omitting all reference to the Opera House, where the patrons of grand drama were provided with a change of bill nightly, I saw the following plays:—

Sunday.

German Playhouse . "Behind the Walls," a Jewish play.

Monday.

Altona Theatre . . "Intrigue and Love," Schiller.

Tuesday.

German Playhouse . "Clavigo," Goethe. / "The Accomplices," Goethe.

Wednesday.

Altona Theatre . . "Faust," Goethe.

Thursday.

German Playhouse . "Love's Labour's Lost," Shakespeare.

Friday.

German Playhouse . "Twelfth Night," Shakespeare.

Altona Theatre . . "Comedy of Errors," (Second piece) Shakespeare.

Saturday (10.30 *a.m.*).

Altona Theatre . . "Romeo and Juliet," (Dress rehearsal) Shakespeare.

Saturday (8 *p.m.*).

Schiller Theatre . . "Wallenstein," Schiller.

Sunday.

Thalia Theatre . . "Lulu," a new play, (Matinée) Wederkinde.

Thalia Theatre . . "Comrades," Strindberg.

The staging in all these plays was a work of art, and complete to the smallest detail. If the presentation of "Love's Labour's Lost" had been seen in London it would have been the talk of the town and would have had a run for over a hundred nights. The acting at all the theatres, if not great, was remarkable for its uniformity, and for the ability each actor had to create character. It must then be admitted that, for the size of the town, the list of classic plays presented in Hamburg in one week was a creditable one. Of course, this list does not exhaust the plays acted during the week; they are only those at which I was present.

To carry out this varied programme, the organisation of the theatre must be highly efficient. In the German playhouses are many officials in black coats and starched collars, and the offices are well furnished with every requisite which an important place of business can require. Work begins at nine in the morning and continues until midnight, although there is some cessation of duties between three o'clock and six o'clock for rest and food. When a new piece is produced, for which time has to be found, in addition to the daily routine that the week's repertory demands, then work of some kind is going on in the building all night as well as all day, and this amazing industry lasts throughout the season, from the first week of September to

the end of May, while in the Christmas-week time has to be found to revive special fairy plays for the young people during the afternoons, in addition to the night's repertory. Without, therefore, a large and capable staff, including several producers and heads of departments, and a director who combines much professional knowledge with business aptitude, the work of the theatres on the Continent could not be done at all, for the loss of half-an-hour in the scheduled time-table would throw the whole day's work out of gear. In Hamburg, too, the curtain rises to the second advertised on the bills, and the play ends at the time indicated on the programme. It can be easily understood, then, that there is no room in any department of the theatre for the laggard, the pleasure seeker, or the physically unfit. They drop out of its machinery from inability to keep up with its duties, because the actor, besides his work in the week's repertory, will be called upon to prepare an important part in a new play, of which he is expected to give a finished performance after some six rehearsals. It is not, then, strange that the actor who has played a long part on one night is glad to escape from the fatigue of his labours by undertaking a small one the next night, for he has abundant opportunities during the season of showing both the management and the public the scope of his talents. And after nine years of incessant toil, if he is worn out and no longer able to keep up his efficiency, he can retire on a small pension, to the capital of which every artist contributes who enters a theatre in Germany, whether he is earning £1 a week or £100.

As the Opera House and Altona Theatre are both under one direction, there are some eight hundred persons receiving salaries, while the subscribers for the season will number more than half a million, and many of these can, for the small sum of 18*s*., secure a reserved seat, which will enable them to see fifteen plays of one series during the season, and choice can be made of the modern, the classic, or the Shakespeare series. There is far more elasticity, too, about the box office in Hamburg than in London. There are the "little prices" (4*d*. to 6*d*.) charged for Sunday afternoons or on *fête* days; there are the "ordinary prices" for short plays; there are the "middle prices" for "Faust" and "Romeo and Juliet," and there are the "great prices" for grand opera, or when it is the first night of a new piece. Then the time of beginning the play varies: "Love's Labour's Lost" begins at eight o'clock and is over at ten o'clock; "Twelfth Night" takes half an hour longer. "Romeo and Juliet," given in nineteen scenes, lasts from seven o'clock until twelve o'clock, and so does "Faust" with its twenty scenes. The audience, moreover, in its behaviour is faultless, and custom here is also law. You must not take your stick or cap into the auditorium with you. You must be in your place before the curtain rises. You must not applaud your favourite actor when he first appears on the stage, nor when he leaves it in the middle of a scene after a clever piece of acting or declamation. You may titter, in the approved Shaw manner, but not laugh outright at the jokes and, above all, you must listen and not miss a word of what your author has to tell you, which he often does at considerable and almost unnecessary length.

The limits of this paper will not allow of a detailed criticism of plays and actors. To speak of my individual preference, I was much struck with the spirit of romp and farce with which the "Comedy of Errors" was rattled through; the whole of it was acted in one setting, and in a little over an hour, as it would have been done in Shakespeare's day; but the archaic and grotesque costumes, I thought, removed the play too far from actual life. The grace and beauty of the scene, costumes, and lighting in "Love's Labour's Lost" I shall never forget, nor yet the perfect balance and restraint of the actors in the Jewish play, and in "Comrades." But what is especially noticeable to the Englishman is the catholicity of taste shown by the playgoer who is called upon to accept so varied a programme. It is impossible to conceive of a Hamburger disliking Shakespeare or Goethe because he likes Strindberg and Schnitzler; his taste is wholesome. To suppose that the town could run mad over one particular author or play, or even actor, seems out of the question.

As regards the people's theatres in Germany, they have a standing of their own due to the character of the audience which is attracted, and which apparently is progressive in the best sense of the word, in so far as it looks to receive from the theatre not only amusement, novelty, morality, but also expects to obtain from it a broader outlook on life; and while these theatres keep the playgoer in touch with Goethe, Schiller, and Shakespeare, they also include in their repertory every modern writer who holds the position of being an accredited dramatist, namely, one who can portray character and incidents which reflect life and enable the onlooker to understand and

appreciate the realities of existence. That is to say, you cannot see in the people's theatres in Germany a single play of the class which appeals to the bulk of the working-classes in England, nor ever see there a play such as "The Great King," which I saw acted at the Royal Court Theatre in Berlin, on what was called a patriotic night. Here the audience was shown Frederick the Great, either playing on his flute or astride his charger; it was an altogether silly affair. What was also noticeable about these people's theatres was the representation in German of the best plays of our own dramatists, such as Shaw and Galsworthy. In Germany, then, there seemed to me to be a people's theatre which fully justified its existence. To watch the workman at the Volkstheater in Berlin, was to appreciate how much the German artisan was in advance of the English mechanic in appreciating the advantages of knowledge. Education through the theatre is so well recognised by the working-classes in Berlin, that they have become a society of playgoers numbering ninety thousand, and recently they have laid the foundation-stone of a new theatre there. For some years now they have been an organised body supporting a theatre with a subscription which amounts to about 4*d.* a performance. Now, what does this mean? That, without the advantages of a college education, the workman in Berlin may be said through his theatre to have a knowledge of the best minds from Æschylus to Ibsen; whereas the English artisan, though enjoying far greater privileges as a citizen, is yet so ignorant of life outside his own political horizon that he really believes that all that is necessary to bring about the millennium is that every living being should be able to think and act exactly as he does himself.

It is interesting to turn from a study of the Continental theatres to those in America, and as it is about ten years since I was on the other side of the "big pond," I must for my information refer you to *The Stage Year Book*, an annual publication which reflects very great credit on the editor, Mr. L. Carson, because in this volume the reader will find well-written summaries by first-class experts of the year's drama, both on the Continent and in America. On the last page of Mr. Denny's article on "The Year's Drama in America," written for the year 1914, is the following paragraph:—

"And so the worst year on record (1913) closed with depleted exchequer in many instances, bankruptcy in others, while never before has it happened that so many actors have been idle at this time of the year, when usually every available artist is occupied. Nor is this the worst phase of the case, since managers have scarcely an attraction that they can count upon to take them safely to the summer, or one that can offer any very great prospect for the road when the present pieces have to be called in."

Then in Mr. Denny's article on "The American Stage," published this year, the opening paragraph states that:—

"The past year (1914) may be looked upon as the most disastrous of any to date, for in no previous year can one remember such general dissatisfaction on the part of the managers, or so much unemployment among the actors."

This, then, was the position of affairs on the stage in America during the years 1913 and 1914. The commercial men who controlled the theatres there, while admitting that their one object was to make the theatres pay by supplying the public with what it wanted, regardless of the restrictions imposed by dramatic art, were yet not able to carry out the work they considered themselves competent to undertake. Nor were these gentlemen conscious of their own shortcomings, nor did they realise that the system on which the theatres in America are worked was not likely, in the long run, to inspire a sane-minded public or a capable manager with confidence.

Playgoers in America are thus encouraged to believe that the success of a play depends, not upon its intrinsic dramatic qualities or the manner in which it is presented, but upon the mood of the audience at the moment—to like this play to-day and to dislike it to-morrow. But audiences of this sort soon cease to use any judgment at all, so that managers look upon their business as a pure gamble, and put up plays altogether regardless of their merit. "Yet," writes Mr. Denny, as to this disastrous year of 1914, "the big bright spot in the theatrical business was the wonderful success of Sir Johnston Forbes Robertson in his Shakespearean repertory." And it might well be so, considering the extent to which the perversion of the art of the theatre is carried by American managers. The following quotations are taken from Mr. Denny's survey for 1914:—

"At the Comedy 'The Marriage Game' was in its last throes, all attempts to bolster it up having failed." We learn in another paragraph what is meant by the term to "bolster up" a play. "The frigid reception accorded the production of 'Kitty Mackay,' in Syracuse,

had the effect of giving the backers cold feet, so that William Eliott, who had picked it out as a possible winner, had to look elsewhere for financial support, and found it in the direction of his brother-in-law, Morris Gest, who took a three-fourth share in it. The New York papers extolled it highly, and the advance booking then went ahead, the hotels and speculators taking deals, with the result that it ran right through the season. One illustrative incident in connection with this piece is the fact that, after it had gained the approval of New York, a company was sent with it again to Syracuse, where it packed the house during the stay, although the actors were said to be inferior to those who appeared at the first visit." And yet another instance. "'Twin Beds' at the Fulton, a comedy by Salusbury Field and Margaret Mayo, made a rather bad start, which induced the producer, William Harris, to part with his right to the authors. Selwyn and Co. took the matter in hand, with the result that it blossomed into a first-class success. It may be as well to mention that Margaret Mayo is Mrs. Edgar Selwyn, so that the position may be thoroughly understood." Here are other items of interest. "A combination in the playbroking business, which took place at this period, promises still further to add to the manager's trouble. An agitation was begun this month among the stock company managers to reduce the fees for plays, which they claimed were out of all proportion to what was right and just, some of the successful attractions claiming £200 for a week's royalties." "A further attempt to stop the ravages of the ticket speculator was made by the District Attorney, but the effort failed by influence brought to bear by the people interested in the ticket speculation business." "'H.M.S Pinafore' was staged as a solidly built ship, floating in the harbour off Portsmouth, and all the visitors to the ship arrived alongside in boats, and clambered on to the ship by gangways, while the crew manned the rigging just as in real life. The production cost an enormous amount of money, and the attraction proved a failure." "The officials of the Catholic Society for the supervision of plays, issued their first White List. It named 130 plays, of which only eight were produced during the season." At the same time America has this advantage over England, that there are more plays by new authors produced and more theatres have stock companies than over here.

In the *Stage Year Book* for 1914, and also for 1915, the survey of our own drama is written by Mr. E. A. Baughan, the dramatic critic of the *Daily News*. There is very little to choose between the methods of theatrical industry in vogue in America and those in England; but the difference in the criticism of the subject by Mr. Baughan and Mr. Denny is obvious. There is no pose about the American; he makes no effort to apply an academic standard to a class of work which he knows is essentially unacademic; nor does he imagine that those of whom he writes regard their work as anything more than a business, about which they have no secrets and make no mysteries. Mr. Baughan, on the contrary, applies dramatic criticism to what is unworthy of it. As a consequence he fails to point out to his readers that in the majority of cases the English manager is not concerned with the quality of the play he produces, because with him the vital question is how to get a play financed. The capital needed for producing and running a play in London, as in America, does not come out of the pockets of the playgoers as it does on the Continent, where the public pays its money in advance in the form of subscriptions for a whole dramatic season. In London, when the play is financed by speculators for a long run, the risk incurred is considerable, and managers have to invent some way to protect themselves. Fortunately for them, Englishmen are so determined to go to the theatre to see what they like, without in the least knowing what it is that they like, that managers have little difficulty in persuading them that they like what is provided for them. Hence arises the theatre system, a subtle and highly organised machinery, controlled by men who often know more about racing and public-houses than they do about drama. Whatever may be the artistic aspirations of an actor-manager, he has to come under the tyranny of this system, or else to face bankruptcy. An exorbitant rent compels him to make "deals" with box-office agents, bill-posting contractors, and other theatrical agencies, who think less about the quality of a play than of the machinery they can put in motion to manufacture the play into a well-talked-of success. Obviously those who capitalise a play are not content to lose their money simply because the critics and first-nighters call it "rubbish"; and in a few weeks it is paragraphed in all the newspapers in the kingdom that the play is filling the house to its utmost capacity—but filling the house with "paper." It is useless, then, to discuss the drama seriously in this country

so long as plays are financed under the present system. Not until it is possible to get rid of the tyranny of the tradesman and the speculator can any improvement be looked for in our theatres. To the financier the repertory theatre offers no attraction, and Germany knows what it is about when it clings so persistently to its system of subscribers. German writers may, therefore, well write :—

"It is becoming harder and harder for private managers to keep their heads above water. In the big towns, especially in Berlin, they are trying to keep things going by means of the long-run system, with all its bad consequences and its entire dependence on a big 'draw,' or else they do their best to win the coy public by catering entirely for its baser wants. That the only real cure for this lies in the municipalising—at least, to a certain extent—of the theatre, the managers are now beginning to realise, and at the yearly meeting of their society a resolution was passed saying that the Society of German Theatre Directors regards it as one of the noblest duties of German towns to work to a much greater extent than heretofore to promote the interests of the German stage! And all the time the towns, quite apart from the ruling princes, are doing a great deal, and in an ever-increasing degree in that direction, knowing that good theatres are good for them and from a business point of view also, because they attract visitors to the town."

This is a public-spirited utterance on the part of German managers which we may look for in vain from among our own actor-managers.

Then, again, the system which is now prevalent of specialising in the choice of artistes tends to injure the art of the theatre, besides being an indignity to the actor. Some time ago Sir George Alexander pointed out that the modern stage was so terribly overcrowded with even really capable people that actors almost tumbled over one another. But it is only necessary to study the advertisement columns of the theatrical newspapers to understand the cause of this overcrowding. Men and women are chosen by managers, not because they can act a variety of characters, but in order to fill one particular part for which some special physical fitness is required. As a consequence, the capable actor is apt to be ousted from his legitimate work to make room for some one who may be a few inches taller or broader than himself. As an illustration I give some examples of the kind of advertisements which appear in English theatrical papers under the column headed "Wanted, Artistes" :—

Wanted.—Character Actor for Seaman; look twenty-five; slight, about 5 ft. 7 ins.

Wanted.—Character Actor, big build, strong voice, for Policeman.

Wanted.—Responsible Actor, age about thirty, height, 5 ft. 10 ins.

Wanted.—Smart Young Actor, look sixteen, to play Boy Scout; also Tall, Responsible Man for Military Officer.

Wanted.—Pretty, Well-shaped Girl, about seventeen (must look younger), height 5 ft. 2 ins.

Wanted.—A Lady over forty years of age, without wrinkles and with a clear, smooth skin.

Wanted.—Character Actress, for Stout, Nagging Housekeeper, look fifty.

Of course, these advertisements were not inserted by West-End managers, who usually secure their artistes through agents, or by direct communication with the performers themselves. And yet even few of our leading managers realise that versatility is the first qualification for an actor, who should be able to impersonate other people besides himself. At present many men and women are induced to enter a precarious profession in order to undertake a part for which they have a personal resemblance while possessing no ability to impersonate character. At the moment, perhaps, it may seem ungracious to call attention to these matters, but it cannot be doubted that the conditions which determine the employment of actors in this country are apt to injure the well-being of the community as well as the art of the theatre. To-day it is not talent which finds its way on to the stage.

And now, for a moment, let us consider what is the attitude of the literary profession towards Shakespeare, the dramatist, actor, and man of the theatre. Jane Welsh Carlyle remarks in one of her published letters that she has been reading "Love's Labour's Lost," and "found it uncommonly dull." Is the play dull, or was the reader's judgment at fault? There are many reasons why reading to oneself from the printed page is an inefficient test of the merit of a play. In the first place, the drama of Shakespeare is written to be spoken and has special laws of its own. There is, so to speak, a grammar for conversation and a grammar for composition, because in one case it is the ear that must be satisfied and in the other the eye. Moreover, when the language to be spoken is verse, harmony and melody become part of the structure, and it is not until the words receive a suitable delivery that they can be fully appreciated. In fact, dramatic poetry, so long as it remains unspoken, to a great extent may be compared with a composer's libretto — it is something that is incomplete. The music, which in this case is elocution, must be added.

Nor can characterisation be treated in drama as a thing apart from elocution. A teacher of a timid disposition and a hesitating manner, with a voice essentially feminine, will never convince her scholars that the hero of Agincourt is a warrior: at least, not when she is reading aloud his battle speeches to a room full of children. The interest of drama depends also upon movement, of which the printed page often gives no information. Action will give point to words which in themselves may be commonplace. It may then justly be inferred that a play originally written to be acted on the stage is not the same thing when it is published to be read. Shakespeare, Molière, and all practical dramatists uphold this assumption.

On the other hand, there will be a legitimate desire to read a play after it has once been acted. The printed play then becomes, in the fullest sense of the word, a libretto. While the eye scans the words in the playbook, the mind recalls the tones of the actor's voice, the movement of the characters, the stage pictures, and then once more the play lives in the reader's mind. Before Ford, Middleton, or Ben Jonson can be read with pleasure by anyone but the expert or the scholar, their plays need to be revived upon the stage. Thousands of copies of the morality play "Everyman" have been sold since its recent revival; but those who read the play without first seeing it acted fail to realise its merit—it does not interest.

It is often stated that it is more profitable to stop at home and read Shakespeare than to go to the theatre and see him acted. But in so far as this question affects the majority of English readers, it may be safely asserted that Shakespeare is not read at home, and Shakespeare will never be read at home in a general way until he is seen oftener acted on the stage under intelligent conditions. A variety of editions of his plays are published yearly, but excepting for class instruction they are not commonly read. If the books are bought by the general public they are bought for the sake of the binding, or the illustrations, or because some popular actor or editor has written the preface: or it may be that the book is purchased merely as an investment, because it may one day sell for more than has been paid for it. Even the standard plays, other than Shakespeare's, which come out occasionally in neat little volumes, so tempting as an ornament to the bookcase, are either not read or not understood. Seeing on one occasion a dainty volume —it was Webster's tragedy "The Duchess of Malfi"—in a bookcase, I remarked to the owner that the play was shortly to be revived by the Elizabethan Stage Society. The book was then taken down and read, and a severe criticism made upon the waste of time and money involved in reviving "such obsolete rubbish!" When also it became known that the society would produce Ben Jonson's "Alchemist," there was shown much eagerness to obtain the newly published edition of the play, and as a consequence the society's secretary was inundated with letters from members complaining of the intention to revive such a dull and uninteresting play. The "Alchemist," however, proved to be, in representation, one of the most amusing of the society's productions. In the face of experience of this kind it is not surprising if one arrives at the conclusion that to publish unacted plays does little to advance the study of classical drama; it is merely a form of literary commercialism. In fact, their publication does the reverse of the good that is intended. The readers like the binding, the pictures, and the preface, but have no good word to say about the play, and no curiosity is excited to see it acted. The special kind of knowledge and imagination which will enable them to understand the play is wanting. To the reader it is as unlike life as the appearance of a skeleton is unlike the symmetry of the human form.

Besides, not only is Shakespeare little read in this country, but the authorised teaching of Shakespeare in our class rooms tends indirectly to banish the poet, not merely from the stage, but also from the reading-room. Here, again, educational commercialism seems to hamper the promotion of real education. The plays of Shakespeare are not brought before students in a way that will, by the quickest and most direct means, establish an interest in his writings. The method of teaching naturally turns upon the question of what is the most vital part of the play—the drama or the literature, the characters and the incidents or the grammar and the philosophy. Shakespeare's philosophy has for so long been the staple theme of commentators that the importance of the play as a story seems to have been forgotten. But Shakespeare's philosophy is not legitimately open to discussion independently of his characters. The dramatist should not be in evidence at all. The ethical value of Shakespeare's plays as a whole, for good or for evil, may occupy the attention of commentators, but it is enough for the reader to know that Hamlet's theory of

suicide is in flat contradiction to that of Edgar in the play of "King Lear," while both views are consistent with the temperaments of the two men speaking them; which view is Shakespeare's it is not our business to know. Perhaps he was too much occupied in creating the opinions of his many and varied characters to have any left for himself. The practice of using Shakespeare's plays to explain the man Shakespeare leads to endless theories of a profitless kind, and leads, besides, to those errors which arise from detaching dialogue from the context and considering it independently of the characters.

It is the fault of educated opinion in this country that everything belonging to the stage is put down on the side of frivolity; it is never regarded as serious work. An advertisement a few years ago was sent by the Elizabethan Stage Society to a college journal published at one of the leading universities announcing a performance of Marlowe's "Edward II." This play, which had not been acted for over three hundred years, was being revived at a summer meeting at Oxford. Yet the advertisement was refused on the ground that "theatrical notices" were not inserted in a paper devoted exclusively to literature and education. Presumably, had a printed copy of the play been advertised, no protest would have been made. In fact, the poetical drama is of no importance in our educational curriculum beyond giving professors opportunities to lecture on it. Plays are to be treated as literary compositions—"Words, words, words!" That which clothes the skeleton, gives it flesh and blood, makes it vital and interesting, is unworthy of academic consideration. No doubt the modern conditions of the stage are not of a kind to arouse interest amongst scholars. They will tell you that our stage is entirely given over to spectacle or farce, and that it is more profitable to stop at home and read Shakespeare's plays than to go and see them acted at the theatre. But, as previously stated, the answer to this argument is that neither publisher nor lecturer can persuade the man in the street to read his Shakespeare. The value of lectures on drama can be summed up in the question, "What are professors of literature, commentators and editors doing to encourage a taste among the people for poetical drama on the stage, the works of Shakespeare, Marlowe, Ben Jonson, Ford, Massinger, Fletcher, Milton, Goldsmith, and Sheridan?" The answer is: "Next to nothing!" Notwithstanding the achievement of nineteenth-century criticism, the labours of historians and editors of Elizabethan drama, and the progress made in the direction of an intelligent appreciation of the chronology of dramatic literature, to none of our men of letters can we give the credit of creating a demand for acting the poetical drama, in the same way that the late Sir George Grove may be said to have made classical music popular. And Sir George Grove was not a musical conductor, nor an impresario, nor even technically a musician; he was a musical critic who, instead of lecturing about Mozart and Beethoven, determined to get the forgotten works of these masters performed. It must be admitted, then, that the main cause of this stagnation in things connected with the higher interests of the stage is to be found in the want of sympathy which exponents of literature show for acted drama. The most pressing need of the moment is to found at our universities a chair of Histrionic Art, so that the talkers on drama may have some knowledge of what they talk about; that they may grasp the fact that there is a distinct art of the drama, with its own principles and its own technique; that they may inculcate respect for this art, and give themselves the opportunity of trying their hands at its form of composition; that they may realise, in fact, what are its real difficulties. Something practical can surely be done to get justice done to Shakespeare's intentions upon the modern stage. If professors of literature made it their business to attend all Shakespearean performances and to criticise them publicly instead of merely ignoring them, managers would then realise that they had something else to reckon with than a theatre full of amusement seekers. Above all things, the man of letters should recognise that if the poetical drama needs for its interpretation on the stage a special school of training for its actors, then scholars and actors must combine to create it; for the one cannot do it without the help of the other. Meanwhile something practical can be done towards securing a larger proportion of intelligent playgoers. Dramatic literature should be studied under more stimulating conditions than it is at present; that is to say, every college should have its "two trestles and a board" from which the poetical drama can be declaimed, and by reviving the art of elocution give to both poetry and drama new life.

But it is contended that Shakespeare is one of the world's three greatest men, and that he is venerated by a large section of the public who

never enter a theatre. From this it is to be inferred that a certain, and by far the largest, section of the British public either objects to Shakespeare's plays being acted on the stage or dislikes seeing them acted there. This, I hold, is an indefensible attitude for the admirers of Shakespeare to assume. It is as unreasonable an argument as it would be to contend that those who wear boots are not indebted to bootmakers. Shakespeare learnt his art in the theatre, and most of his plays are built upon the foundation of older ones. It is inartistic to criticise his poetry apart from his plays. The injury done to his drama by such treatment is expressed with admirable insight in a letter I received from the accomplished actress, Miss Constance Collier, and which is here read with her permission :—

"I am absolutely in sympathy with what you say. Shakespeare was an actor, and wrote his plays for actors, to be acted in the theatre. It is entirely through the academic attitude of the gentlemen who expound him to us from the study that the deadening, bent-knee attitude towards Shakespeare in the public mind has arisen. It is an uncomfortable position to be on one's knees perpetually; that is why audiences keep away, and shirk the support of Shakespeare.

"Whenever he is produced in the theatre by a man who understands the theatre, the audience love him, and are surprised by him anew—his gaiety, his humanity, his optimism, his humour. The only thing one has to get over in the audience is the deadening reverence that has been taught them by the literary mind towards Shakespeare in their youth. They have been taught him in their schools by the undramatic mind. Poor Shakespeare has been analysed and pulled to pieces and dissected and put together again, and all that they realise of his beauty and charm and dramatic power is intense stodginess.

"It is absolutely essential that the drama and dramatic plays should be taught by dramatic teachers. It is better to send a sailor up a mast than a tailor.

"There is a certain air of patronage towards the theatre in England to-day, particularly among literary people. It is curious and very funny, when one remembers that both Shakespeare and Molière were actors. The Shakespeare celebrations should certainly be in honour of our profession and our profession should be at the head of them."

After all, is it not an incongruous procedure to wrest the dramatic poet from his proper environment, the stage—a place which has been appropriately named a mirror, because it professes to reflect life in all its aspects without favour or prejudice? There is only one Shakespeare to whom Englishmen can pay homage in 1916, without at the same time showing disrespect to his memory, and that is to Shakespeare, "the supreme dramatic artist." In Germany he is so acknowledged, and why not also in his own country? Professor Brandle, speaking before the members of the British Academy in London two years ago, said :—

"The blessings of a repertory theatre, and the best portions of modern German literature, we owe principally to Shakespeare. He has given us the plays which at the outset drew the largest audiences, trained the best actors and critics, and which were taken as models by the more gifted playwrights. The theatre is the stronghold of the Shakespeare cult in Germany."

And George Brandes, when lecturing in this country, said: "It is forgotten, here, that Shakespeare wrote plays to be acted." Surely this forgetfulness is in a great measure due to the persistent way in which our educationalists ignore the stage on every occasion when reference is made to the dramatist, either in print or in the class-room.

Perhaps it has hardly yet dawned upon the dramatic profession, as a whole, what is its opportunity in 1916, and what it stands to lose by neglecting to take a step forward, and to shake off the influence which has so persistently overshadowed the genius of the English stage, and refused it the right to be guardian of Shakespeare's reputation. If it is the business and duty of the literary profession to make itself responsible to the country for the interpretation and appreciation of the poet's plays, then the dramatic profession has no status, and our theatre is merely a theatrical industry. But Shakespeare is not only the foundation-stone of the modern theatre, he is also the keystone of it, for his supremacy in the theatre is admitted in every country but his own. And whatever shortcomings in the representation of the dramatist's plays may be brought against the English theatre, they are chiefly due to those educationalists who forget that it is both the business and the duty of the stage to treat Shakespeare's plays with respect and intelligence, whenever and wherever they are acted. But it is scarcely reassuring to find the meeting on July 3rd, 1914, at the British Academy, thus reported in a prominent London daily paper :—

"The matter of the speeches, no less than the distinction of the orators, rose to the occasion yesterday at the Royal Society's meeting in connection with the approaching Shakespeare Tercentenary. Evidently something worthy is going to be done in 1916. With two or three honourable exceptions, our theatrical managers may leave

Shakespeare alone, but the people read him more and more, and he grows ever increasingly a part of the national life and spirit."

Perhaps no more inaccurate statement ever got into print—at least, not in my own experience. It is true that there is an immense amount of writing and talking about Shakespeare now going on, but not 2 per cent. of it has any connection with his plays; nor have I any recollection of coming into contact with a single individual who reads Shakespeare except for professional, or under compulsory, reasons.

Let me conclude by asking those present to take away with them, for the sake of remembrance, the following five sentences, as summing up what is vital in my address:—

1. *The theatrical industry as it exists in England to-day.*—I ask you to connect with this sentence the words of Sir Philip Sidney: "What is birth to a man if it shall be a stain to his dead ancestor to have left such an offspring?"

2. *The present status of the actor.*—Let us add to this sentence the words of Hazlitt: "Players are not as respectable as a profession as they might be only because the profession is not respected as it ought to be."

3. *The attitude of Shakespeare towards the learned professions in his own country.*—Clifford Harrison's words may here, I think, appropriately be quoted: "I have an almost measureless admiration for scholasticism, but I have also a bitter envy of it, and an inborn antagonism to it."

4. *The real Shakespeare.*—"Soul of the age, the applause, delight, the wonder of our Stage." These are the words of Shakespeare's most intimate friend and contemporary, Ben Jonson.

5. *Conclusion.*—That in the coming Shakespeare Tercentenary Celebrations, it is vital to the best interests of the stage that Shakespeare's name shall be immediately connected with the modern English theatre of which he himself, actor and part theatre manager, as well as dramatic poets is the founder, inspirer and highest ornament.

DISCUSSION.

MR. BERNARD SHAW said the occasion was a very interesting one to himself, because it had brought together in public the Chairman and the author of the paper. Despite the fact that their connection with his (the speaker's) own profession —that of the theatre—was so very conspicuous, this was probably their first meeting. In any period in which art was active there were two orbits which never crossed one another. One was the orbit of the man who dealt with an established form of art and carried it to its highest consummation and perfection — always, he might say, a contemporary form of art— always working with actually living persons in an art which belonged to their own period. The other was the orbit of the man who, finding the established forms of the art altogether repugnant and impossible to him, and believing them to be entirely wrong from beginning to end, immediately started on a forlorn hope and tried to turn the public taste upside down. In the present day the first orbit was that of Sir Squire Bancroft, and the second orbit was that of Mr. William Poel, who had made the very great mistake that day of not talking a great deal more about himself and about his own career. When he (the speaker) first came to London he saw with great delight and pleasure the theatrical art as presented by Sir Squire Bancroft at a pitch of perfection from which it had never descended. Afterwards Mr. and Mrs. Kendal and Sir John Hare carried on the traditions very excellently and beautifully, but Sir Squire Bancroft had reached a summit in art beyond which there was no progress. Sir Squire Bancroft had worked hand in hand with his author, Robertson, who wrote his plays for the sort of stage that Sir Squire handled so well. Some people used to say that this stage was a stage of illusion—a thing which he (the speaker) altogether demurred to. In a drama written by Robertson and handled by Sir Squire Bancroft there was no illusion on the stage at all; what was seen was the actual thing. A room was seen on the stage; the actual walls were seen. It was true they were not made of brick and mortar, but only of canvas; but if the audience looked at the walls of the room they were at present in they would not see the brick and mortar, but only the applied paint or paper, and that applied paint or paper was what they saw on the stage. When he produced a play, he had to select the wallpaper exactly as if it were for a real house, except that he chose it with reference to the taste of the persons in the play and not according to his own. People said that rooms on the stage were not real because they had only three walls. He would give a five-pound note to any member of the audience who could see at the same time the four walls of the room in which they were at present. As he had said, there was no question of illusion in the matter. There was the real thing. Most modern plays, including his own, were written for that particular kind of production. The art of that production, as practised by Sir Squire Bancroft, working hand in hand with his author, Robertson, had reached a point that had never been surpassed. When it came to dealing with Shakespeare it was a different thing. When he (the speaker) first saw Shakespeare on the London stage, never for one moment was Shakespeare really there at all. There was no illusion. The more they tried to produce illusion by scenery the less illusion there really was. Performances could be made interesting by an individual actor of extraordinary power and attraction, but it was always the actor who had to do it. He had seen Shakespeare acted with scenic arrangements which would be inconceivable

to the younger members of the audience who were present that afternoon. He was quite familiar in his youth with the changing of scenes and the pushing on and off of flats in full view of the audience. But even if an actor of extraordinary power and attraction was there, the audience did not get Shakespeare, as, with all the shifting and changing of scenery and the thing being arranged in the way in which it was, about one-third of the play was cut out. Now that was where Mr. Poel came in. He was the man who really did understand that that kind of Shakespeare, except as a sort of springboard for an individual actor of extraordinary talent, was unendurable; and with very inadequate resources he had gradually got at the people who really loved Shakespeare, and given them Shakespeare's plays as Shakespeare intended them to be played. There were very few Shakespeare lovers. He (the speaker) was very happy to say that he was one, and another was Mr. Granville Barker, who was at the present time giving performances of Shakespeare in New York with great success, just as he had given them in London, from one end to the other, without one line being left out. And Mr. Granville Barker began as one of Mr. Poel's Elizabethan stage players, and was always proud to acknowledge his debt to Mr. Poel. He (the speaker) would end as he began. The two orbits had never crossed. As far as he knew, the Chairman and Mr. Poel had never met before; and that was a fact which made the occasion an extraordinarily interesting one. Personally, he felt a very great regard for both gentlemen, and professionally the deepest gratitude to them; and if anything in the nature of a vote of thanks were to be moved, it would be impossible for him to discriminate between the two, as they had done superb work for the theatre in their own particular ways.

A vote of thanks to the author for his interesting paper was then put, and carried with acclamation, for which Mr. Poel briefly returned thanks.

THE CHAIRMAN (Sir Squire Bancroft) said he rather regretted the paper had had to be read on a Wednesday afternoon, as it deprived those members of his profession who were now more prominently before the public than he himself was of the opportunity of being present and making any remarks on the paper. He hoped Mr. Poel would forgive him if he said, in all friendliness, that he was a little "fed up" with Germany. He admitted frankly that he was not in the mood to consider or reflect upon the culture of that nation until our heel had trodden upon her militarism. When that was done, once and for all, he would be better able to listen to all the greatness which belonged to her. He desired to thank Mr. Bernard Shaw for his kind remarks, although most of them should have referred to his wife and not to himself. It was she who discovered Mr. Robertson, and in illustrating him he was only too proud to have the privilege and the honour of working by both their sides. With regard to the immortal name of our greatest poet, he could only say that he should for ever feel proud to think that he had been what William Shakespeare was—an actor.

CANADIAN INDEBTEDNESS.*

In the course of the past summer I visited Canada, partly with a view to investigating upon the spot the opportunities which the Dominion might afford for mortgage investments, and partly in order to gain, at first hand, knowledge of the general financial conditions of the country.

In the course of my tour I travelled right across Canada from Quebec on the East to Vancouver City and Victoria on the West, visiting the principal towns of the various districts, interviewing bankers and leading citizens everywhere, and endeavouring to master the intricacies of the legal procedure involved in carrying out mortgage transactions in Canada.

It is difficult to convey any adequate idea of the vast size of the Dominion, or of the great distances which separate the chief towns from one another. But Quebec is as far from Vancouver as from London, and the journey by the quickest train takes five full days of continuous travel.

It should be borne in mind that my visit was made at a time when many circumstances combined to render the financial position of Canada extremely unsatisfactory. The gradually increasing land boom and real estate speculation, which culminated in 1912, were followed by a great collapse, the effect of which soon showed itself upon all the business interests of the Dominion. In particular, the absence of dealings in real estate caused a cessation of building operations in the prairie provinces, and this in its turn led to severe depression in the lumber trade of the West, so that wide-spread unemployment immediately followed.

In an extremely interesting speech dealing with the conditions in Canada a few months before the outbreak of war, the Hon. Sidney Peel, President of the Trust and Loan Company of Canada, said:—

"The collapse of this land boom has had the usual effects. Many people find themselves landed with real estate at prices which they can never recover and with instalments to pay which they undertook with a light heart in the hope of being able to pass their purchase on to someone even

* Abstract of a paper on "Canadian Mortgages regarded as a Field for the Investment of the Funds of British Life Assurance Companies, with some General Notes on Canadian Indebtedness," read before the Institute of Actuaries by Arthur Digby Besant, B.A., F.I.A., General Manager and Actuary, Clerical, Medical and General Life Assurance Society, on December 21st, 1914.

more speculative than themselves . . . . . The collapse of a boom brings difficulties, but times of stringency are, as I have pointed out before now, by no means unfavourable to mortgage companies. They can choose their investments and make them at good rates and on reduced valuations."

At the beginning of the summer it was thought that the worst stage had passed and that improvement was setting in; but all hope of this was destroyed by the war, and since then the depression has gradually increased. Under the circumstances it is inevitable that this paper must present a somewhat gloomy picture of the conditions existing to-day.

Canadian Indebtedness.

The growth of Canadian indebtedness during recent years has aroused much interest, mingled with some anxiety, and a few general notes on the subject may therefore not be inopportune.

It is far from easy to ascertain the full extent of Canadian borrowings, for, apart from the large loans which have been floated on the London market, amounting now to five hundred and fifteen millions sterling, it is estimated by Sir George Paish that upwards of one hundred millions sterling of American capital has been invested in the country, and that not far short of another one hundred millions has been lent, much of it privately, on mortgages of real estate and by way of loans to farmers. The total amount of foreign capital supplied to Canada thus amounted at the end of the year 1913 to nearly seven hundred millions sterling, carrying with it an interest burden of about thirty-two millions sterling per annum. It is startling to find that one-half of this great sum has been lent within the past seven years. Reckoning dollars at five to the £, these loans may, roughly speaking, be analysed as follows:—

(*a*) Dominion Government (net)	£70,000,000
(*b*) Provincial Governments . .	26,000,000
(*c*) Municipalities . . . (say)	70,000,000
(*d*) Railways	300,000,000
(*e*) Industrial companies and real estate mortgages . . (say)	234,000,000
Total . . .	£700,000,000

It is not, however, sufficient to regard merely the amount of the debt; we must also take into account the assets which it represents, and endeavour to trace whether the heavy borrowings necessitated by the growth and development of a new country have been justified. That there has been extravagance in some quarters is undoubted; and certain industrial and other loans which have involved the lenders in heavy loss have been open to severe criticism.

But taking a broad view, there can, I think, be no question that the bulk of the immense amount of capital poured into Canada in recent years has been wisely expended. Much of the borrowings by the Dominion Government has been spent upon remunerative enterprise and public works represented by tangible assets. This applies also to the greater part of the debt incurred by the Provinces. The portion of the Dominion and Provincial Government expenditure most open to criticism is that made in respect of certain railways where there seems little prospect of an adequate return on the capital expended. There will be much more divergence of opinion in this country as to the wisdom of much of the municipal expenditure.

A notable feature of the past few years has been the increased attention which British capitalists have devoted to industrial development in the Dominion. Large sums have also been lent to farmers in the prairie provinces, and this expenditure should prove remunerative to the lenders as well as advantageous to Canada.

Dominion Debt.

From the figures presented by the Hon. W. T. White, the Minister of Finance, it would appear that the Dominion debt has shown very little growth during the past few years, and that against the one hundred millions of liabilities there is a set-off of over thirty millions of assets consisting of Sinking Fund, Specie Reserve and miscellaneous investments, so that the net debt is really under seventy millons sterling.

Most of this debt has been incurred for developing and opening up the country, and in view of the enormous size of the Dominion its amount may certainly be considered at the present time as not only legitimate, but moderate, seeing that the Dominion Government supplies large subsidies for capital outlays upon the larger public works and national undertakings.

As the Dominion Government does not levy direct taxation, but obtains nearly the whole of its revenue from customs and excise, the falling off in imports arising from the outbreak of hostilities will cause a serious loss of income, while concurrently the expenditure for war purposes will be very heavy. It seems inevitable, therefore, that even if some of the expenditure on new public works can be postponed, the near future must show a large increase in the Dominion debt.

Provincial Debt.

The Provinces in Canada are independent countries so far as their internal government is concerned.

They, like the Dominion, practically levy no direct taxation, and their chief sources of revenue are the Dominion subsidy, the proceeds of the sales of land, timber and mining royalties, succession duties, fees and licenses. The chief items of expenditure are public works (roads, bridges and ferries), legislation, administration of justice, provision of hospitals and asylums, and large subsidies for education. In most of the Provinces expenditure slightly exceeds income.

The total provincial funded debt in December, 1913, was twenty-six millions sterling, of which eighteen millions had been raised in London. Two

years previously the London debt was fourteen millions, and in 1902 under ten millions. The increase in the indebtedness is spread over the whole country, though it is most marked in the newer Provinces of the West. The eight millions raised outside London have gone chiefly to the Provinces of Ontario and Alberta.

In addition to these direct obligations, the Provinces have guaranteed the principal and interest of thirty-six millions of railway securities, chiefly to facilitate the construction of branch lines of the Canadian Northern and Grand Trunk Pacific.

The Provinces have expended money lavishly in the erection of palatial parliamentary buildings, and the public offices generally are built on an extravagant scale. The rivalry between the Provinces and the universal love of display have undoubtedly led to extravagance in many directions.

Municipal Debt.

The municipal indebtedness of Canada, according to Messrs. Wood, Gundy and Co.'s statistics, had in December, 1913, reached the total of over 102 millions sterling. Twelve millions of this is termed "Local Improvement" debt and is charged primarily upon the owners of the property benefited by the expenditure, though, of course, in the last resort the municipality would be liable. Of the 102 millions, only 40 millions have been publicly raised in the London market, and I think that it will come as an unpleasant surprise to investors in this country to find that this huge additional liability exists.

The total of the London loans two years previously, *i.e.*, at the end of 1911, was 22½ millions, while in 1906 and in 1901 it was under nine millions. It is very significant to notice that during the five years 1902–1906 inclusive, the amount of the indebtedness was virtually stationary so far as the London market was concerned. The explanation seems to be that such loans as were required in that period were absorbed by Canada herself. The era of expansion of municipal borrowing in London began about 1907 and, as will be observed, developed with extraordinary rapidity during the years 1912 and 1913.

The 36 millions which have been raised by these cities either publicly or privately outside London were issued chiefly in Canada or in the United States, and while the latter country is a large permanent holder of these bonds, there is no doubt that a considerable proportion of the remainder ultimately found purchasers in England.

The remainder of Canada's municipal debt, amounting to about 26 millions, is spread over 838 cities, towns and villages, embracing practically every place with a population of 1,000 and upwards.

In addition to the funded debt there are outstanding City Treasury Bills amounting to just under two million pounds.

Much of this expenditure of a hundred millions has been incurred for remunerative enterprises, for, whether rightly or wrongly, municipal ownership of all "Public Utilities" is regarded, especially in the West, as being advantageous to the community. Many new towns have, therefore, been provided with municipal water, electric light, electric tram-cars, telephones, etc., indeed, with all the comforts enjoyed by cities of much older foundation. Up to a certain point this policy may be justified, but in many instances it has been carried far beyond the limits of prudence.

The municipalities impose direct taxation by means of what is known as the Corporation Tax, and out of this all payments for police, sewage, lighting, improvements and general administrative expenses are met. This tax is based upon the assessed capital value of all land and buildings within the areas under the municipal control. A special tax, based upon the same principle, is levied for education. Generally speaking, Canadian municipalities are allowed to borrow up to something like 20 per cent. of the assessed capital value. It will thus be seen that the temptation to raise the assessed value in order to increase their borrowing powers is very great.

I found that there was a consensus of Canadian opinion that in the last few years money has been lent far too freely by England, and on far too cheap terms, especially to the small new cities.

The rapid growth of Canadian municipal indebtedness during recent years has excited a good deal of uneasiness in this country, and many months before the outbreak of war the terms on which such loans were taken up by the London market had grown so onerous that a slackening in the stream of new issues had become inevitable. The war, coming without any warning, has suddenly caused a complete stoppage in the importation of money, and the effect upon the municipalities has been immediate and severe. They were caught unprepared, and works of "Public Utilities" of every description are either suspended or are being completed by means of short-dated loans at ruinously high rates of interest. Unemployment in the towns is already so rife that every effort is being made by the municipalities to continue whatever work is in progress, but there can be no doubt that some of the more heavily indebted towns have an anxious winter before them. Municipal income is now falling off owing to difficulty in collecting the taxes, and for the first time expenditure has to be paid for out of income, since fresh loans are no longer available. So far there has been no default; but the full effect upon Canadian municipal finance of the absence of new loans has yet to be seen.

Canadian Railways.

The latest official figures published deal with the railway statistics for the year ending June 30th, 1913. At that date the mileage operated was over 29,000, and a further 18,600 was either projected or under construction.

The capital liabilities of the Canadian railways amounted to three hundred and ten millions sterling, made up as follows :—

Funded debt (bonds, &c.) . .	£125,000,000
Debenture stock (C.P.R.). . .	33,000,000
Stocks	152,000,000
Total . . .	£310,000,000

Of the above, the bonds and stocks outstanding on account of lines under construction amounted to £36,000,000, so that the capital account of operating railways was £274,000,000.

The average rate of interest paid on the funded debt was just over 4 per cent., and it is satisfactory to note the official statement that the full interest was paid on all outstanding bonds.

In considering the prospects of the railways throughout Canada the question of the harvest in the Prairie Provinces is a factor of the utmost importance. It must be remembered that, great as is the output of wheat at the present time, the area of cultivated land does not represent more than a fraction of that suited for the production of wheat, and there can be little doubt that, as the population increases and a larger area comes under cultivation, there must be a great corresponding development of the railway system. The construction of branch lines in every direction will need much further capital in the future. Possibly at the outset these lines may not be remunerative, but they will lead to the more rapid development of the districts through which they pass, and ultimately should justify the capital expended on them.

The opening of the Panama Canal obviously cannot fail to affect the Canadian railway system, but it is yet far too early to hazard an opinion as to whether the changes will be favourable or adverse. From different quarters I heard the most diverse views on this subject. It appears to be generally agreed, however, that so far as British Columbia is concerned the opening of the Canal will be advantageous and will lead to a great development of the fishing, fruit and mineral industries, and that the railways operating in those districts should be helped thereby.

Industrial Companies.

While England has taken the chief share in financing the railroads and in purchasing Government and municipal securities, the capital provided by the United States has been more largely employed in promoting industrial enterprise. This is perfectly natural, for their means of obtaining local information as to industrial opportunities have, of course, been far more numerous than those open to English investors

The magnitude, however, of the monetary interests involved is very large, for upwards of sixty to seventy millions of American capital, seventy millions of British, and ten millions of European capital have been lent for the development of hydro-electric works, coal mines, iron and steel industries, lumber, pulp and paper industries, fisheries, milling industries, various lines of manufacture and other more or less local and domestic enterprises.

Real Estate Mortgages.

Canadian loans on landed property fall into three main groups, secured respectively upon (*a*) central city property, (*b*) residential city property, and (*c*) farm lands.

Loans on central city property are similar to many of our home mortgages, and thus instinctively appeal to us more than the other types. Under the fairly settled permanent conditions which are found in a relatively old city like Montreal these loans are undoubtedly good, but in the West I regard them as being speculative in the extreme, for valuations made up to a year or two ago have been based upon an inflated standard which has to-day utterly collapsed and has not yet reached any new level of stability. The yield is 6 per cent. and upwards under normal conditions.

Loans on residential city property are regarded by many Canadian authorities as affording security of the highest class, and in the wealthy suburbs of the more important Canadian cities, where the population has hitherto been rapidly increasing, and where the demand for such houses has so far been greater than the supply, it seems reasonable to regard such residential property as likely to continue to appreciate steadily in value, and thus to form a satisfactory field for investment. The rate of interest yielded on this type of security varies from 6 per cent. to 7 per cent. under normal conditions at Montreal, and is a little higher at Winnipeg and Vancouver.

Loans secured on farm lands are largely granted in the Prairie Provinces, and although very foreign to our preconceived ideas at home, have much to recommend them.

The chief advantage of this type of security is that there is not the same danger of inflated values as is met with in town plots, and further, that as the loan is used to improve the land, the security for the mortgage is thereby automatically increased.

Local knowledge is essential for success in granting loans of this character, and the only way in which such business can be safely conducted is to place entire confidence in a responsible local agent and to act implicitly on his advice. Allowing for agent's commission, the yield on loans of this character would be about 6 per cent. for the first year and 7 per cent. thereafter.

Modes of Investment.

In the United Kingdom loans on landed property are usually granted by way of a direct mortgage, but there are a great many difficulties in adopting this method in Canada. These arise from the fact that the systems of land tenure differ widely in the various provinces, and in many cases the formalities can hardly be complied with unless the lender is on the spot. It has thus come about that

private lenders prefer to carry out such loans through the medium of a Trust Company.

These companies fulfil a very special function in Canada, seeing that the banks are not allowed to make advances upon land. The banks get over the difficulty by forming a subsidiary trust company. Thus the Royal Trust Company is to all intents and purposes the Bank of Montreal. A trust company merely acts as an agent for its clients. It undertakes the investment of money, investigates titles, arranges valuations and carries through all the preliminaries. It does not undertake liability for the loans in any way; it merely uses its machinery in the interests of its clients and does its best for them. It is remunerated by a commission on the loan, and by an annual payment for collection of interest and for general supervision.

Undoubtedly the machinery of such a company as the Royal Trust is at least as effective as that of any local board—probably much more effective. The disadvantage of the system is that the mortgages must all be granted in the name of the Trust Company. In fact, the name of the lender would not appear publicly at all, and it will thus be seen how entirely he would depend upon the good faith of the Trust Company.

In conducting mortgage business in Canada the essential points to be borne in mind are –(1) The danger of inflated valuations, especially in the Western cities; and (2) the need of adequate local supervision. For the moment the second point is the more important, for in the present depression of the real estate market values fixed a few years ago are crumbling and will continue to fall until they reach a natural level.

I regard the appointment of a local board or of a representative in whose judgment complete reliance can be placed, and must be placed, as the only means by which mortgages of a safe and high-class character can be secured in the Canadian cities. And this, in my judgment, is a permanent condition, for, as I was so often reminded during my tour, you cannot exercise much supervision in selecting the right or in avoiding the wrong mortgages if you are 3,000 or 5,000 miles away.

SUMMARY.

I will close this paper with some general observations on the Canadian financial outlook. For much information set out in the notes which follow I am indebted to Sir Frederick Williams-Taylor, the General Manager of the Bank of Montreal.

(1) Canada is at present passing through a very adverse time, and the present winter will be a period of grave anxiety.

(2) So far the Eastern cities are standing the strain much better than those of the Middle and the West, partly because of their manufacturing industries and partly because they have had time to accumulate some reserve of wealth.

(3) In spite of the development of the farming industry in the Prairie Provinces, the population in the cities has been increasing much more rapidly than in the country. It is hoped that the present depression will force men on to the land, so that they may become producers instead of merely distributors of wealth.

(4) The total amount of English capital publicly invested in Canada amounted, in December, 1913, to over five hundred millions sterling, many millions of which have been wasted in municipal and industrial enterprises.

(5) In 1913 English capital poured into the country at the rate of six millions sterling a month. This has suddenly stopped, and few Canadians recognise how enormously the industries of the country have depended upon this constant influx of new capital.

(6) The indebtedness of Canada to England involves a monthly payment for interest of two millions sterling.

(7) The payments for war expenses have now to be met in addition. Every gift of Canada to the Empire will have to be met ultimately by a loan in London.

(8) Canada will now go through a time of severe trial in attempting to meet expenditure out of income instead of out of loan, and the intensity of the strain will increase with every day's duration of the war.

(9) It has already been found necessary to adopt a moratorium in the Prairie Provinces to suspend the due payment of interest and instalments of purchase money on land loans, and even in the East there is a strong agitation in favour of some similar legislation for the relief of distressed borrowers.

(10) "Unfortunately economy is not a popular text in a country that has been borrowing so freely for so long."—(The *Economist*, October 24th, 1914.)

These are the adverse facts, and it is well to face them. But I want you to bear in mind that these difficulties are temporary and will pass away. The natural wealth of Canada is enormous, and she will emerge a healthier, stronger, and more self-reliant nation. The greatest asset of Canada is her annual harvest, and, in comparison with the value of this, municipal extravagance can hardly be said to be of fundamental importance. The harvest this season is inferior in quantity to that of last year, but prices are so much higher on account of the war that the farmer is prospering.

Moreover, in considering the future, it must be remembered that so far mineral and even agricultural development is in its infancy. But the spirit of confidence in the future of the country is universal, and shrewd observers welcome the check to speculation which the present set-back has caused and the impetus it has given to the movement for forcing men on to the land.

In summing up impressions of Canada we have to remember, as Sir F. Williams-Taylor reminded me, that we are dealing with a vast country and that we must avoid thinking parochially. There have been periods of depression before and they

have passed. In the same way every Canadian believes that this one will pass in its turn, and that a new era of development and prosperity lies ahead.

ENGLAND AND THE PERSIAN GULF.

The return of the Indian Viceroy to India from the Persian Gulf and his decoration of the chiefs who have shown their loyalty and good service in the recent operations in those regions, coupled with his carefully weighed address to the deputation at Busrah, seem to leave no room for doubt as to the pending annexation of that notable port and province. Lord Hardinge is not the first Governor-General who has been quick to mark his appreciation of the political importance to India of the island and small States dotted about the Gulf. Over a hundred years ago Warren Hastings laid down his firm conviction that these regions were intimately related with Hindostan, and their mastery was a matter of great consideration to the predominant Power in the East. In fact, Warren Hastings's statement of policy differed but slightly from that laid down by us a few years ago, and the recent visit of the Viceroy has cemented our ties with our Persian and Arabian outposts of Empire. At the south-eastern extremity of the Gulf we have Muscat, which, though not actually British territory, is now more completely within our control and restricted from scattering broadcast its former exports of guns and ammunition. Northwards along the Arabian coast we have the Bahrein Islands, over whose trade we keep watch and act as maritime police, while still further to the north-west lies Koweit, the small independent State

under our protectorate, whose harbour is the best in the Gulf. On several occasions the Turks have tried to lay claim to authority over this district, but these pretensions we have always firmly repudiated, and now that the Sheikh has been created a K.C.S.I. by Lord Hardinge the State is still more firmly linked to our cause. Proceeding up the Shatt-ul-Arab, we eventually arrive at Basra, which, with Kurnah, is in our own actual possession and marks our headship of authority, whence proclamations and orders will now issue. It is interesting to recall that Basra actually belonged to the East India Company as far back as the eighteenth century, and its reversion to its former masters is a significant movement of the times. On the Persian side the more important signs of British settlements in evidence are Mohammerah and the Anglo-Persian oil works, while further south are Bushire, Lingah, and, finally, Bunder Abbas at the extreme south. All these ports mark points which will need linking up by improved communications. In connection with these events one must note with regret the death of Captain W. H. J. Shakespeare, C.I.E., late Resident at Koweit, who was killed in action on January 24th, and whose distinguished service in the Indian Political Department and useful services in this region, together with his recent expedition and travels throughout Arabia, have attracted much attention. Lastly, we can scarcely avoid noticing the interesting anticipations formed in some of the Indian journals, who are naturally following the course of events with keen attention, that the future of Mesopotamia concerns the Government of India in more ways than one. The restoration of the irrigation works, designed by Sir William Willcocks under the Turkish authority, calls urgently for completion under its new mastership, while the scanty population of Mesopotamia, once the granary of the East, would supply room for many millions of Indian emigrants, for whom there is no possibility of large new irrigation works.

THE ESPARTO INDUSTRY IN SPAIN.

Among the more important industries of the Province of Almeria, and one upon which thousands of its inhabitants depend for livelihood, is the gathering and manufacture of esparto, a coarse grass with a round flexible stem, which, under favourable conditions, grows to a height of three feet, but whose general average height ranges from twelve to eighteen inches. Although it is an extremely hardy plant and capable of making a thrifty growth even on the arid mountain sides of the interior of the province, yet the esparto grown in regions where the rainfall is more abundant develops to a much greater height. It is found in varying quantities on most of the uncultivated land. Esparto grows in isolated clusters, and, unlike ordinary grass, it does not cover the ground with a mat of roots. The esparto on the lowlands near the sea develops earlier in the season, and grows larger than the product found in the mountainous regions of the interior.

The harvesting of esparto begins in May, according to the American Consular Agent in Almeria, and continues until December. The plant is perennial, and grows during the summer months and in the spring. In gathering, the workman holds in one hand a short stick; by a twist of the hand and wrist he wraps the grass round the stick once or twice, then gives a quick upward pull, separating the stems at the joints near the surface of the soil. It happens sometimes that if the workman is not careful the grass is pulled up by the roots, which not only injures the future crop, but lowers the quality of the esparto, as it is necessary to eliminate the roots and adhering partly decayed grass, the paper manufacturers not being able to use these portions. The esparto lands belong in part to the municipal government, and in part to private individuals. As a general rule the lands are awarded for exploitation to the highest bidders for a fixed period of years; these tenants exploit the leased property on their own account, employing workmen to pull the grass at harvest time. These workmen receive from ninepence to one shilling for gathering a quintal (100 lbs.) of esparto, and are able to earn from two shillings to two shillings and sixpence a day, depending upon the size of the grass, the proximity of the bunches, the dexterity of the workman, and other factors.

Once the grass has been pulled it is tied into straight bundles or sheaves containing several pounds each. The esparto is then conveyed to the nearest factory. There are at present in the city of Almeria three important esparto factories, employing from one hundred to two hundred persons each: in these factories the esparto is cleaned, assorted, classified, and baled, preparatory to shipment to the paper manufacturers in the British Isles. There are also a number of smaller factories engaged in making esparto ropes, baskets, rugs, carpets, saddles, saddle-bags, and numerous other articles used in households and in the industries; these articles of esparto can be constructed at very low cost, and possess remarkable qualities of durability and flexibility. The value of the domestic esparto delivered at the factory at Almeria ranges from two shillings and sixpence to three shillings and fourpence per quintal (100 lbs.). Nearly all the work of assorting and cleaning the esparto in the factories is done by girls and women, who usually work in couples, one picking out the heckle (esparto wild roots), and the other separating the bright new stems from the old and those unfit for paper-making on account of the absence of cellulose.

The work is done on long wooden tables, each girl being assigned to her own place and her own operation, and with her partner working on her own account by the piece. An experienced girl with close application may earn from one shilling

and eightpence to two shillings a day; but the work is very trying to the eyes. The bright new stems are known as "Class No. 1," and the inferior as "Class No. 2." After the grass has been selected and classified it is tied into bundles, and is then ready for final inspection, after which it goes to the baler. Grass with roots is sent to the "heckling" department, where the roots are removed by striking them on a fixed iron comb standing upright on a frame. The roots, with other waste materials, are used as bedding for live stock. Class No. 2, composed principally of old dry grass, is unfit for paper-making, and is therefore thrown aside and used for basket and rope-making. The baling apparatus consists of a heavy horizontal press, cubical in shape, and measuring somewhat over four feet each way. The small sheaves are placed in their proper position in this press and trampled down by a man, and a heavy iron weight is screwed down. The cords used for binding the bales consist of esparto ropes, which are securely fastened by hand while the bale is being compressed. This operation completed, the bale is removed from the press, weighed, registered, and sent to the storage department. A bale on an average weighs 385 lbs. It is claimed that most of the eye diseases, and cases of partial and total blindness, which are prevalent in the city and the province of Almeria, are caused by the poisonous dust coming from the esparto as it is being handled in the field and factory.

VINTAGE IN ITALY, 1914.

Notwithstanding that last year's vintage in France was an exceptionally good one, that in Italy does not appear to have reached the average.

The official returns lately issued estimate the total production last year at 43,046 thousand hectolitres (947,012,000 gallons), as compared with 52,240 thousand hectolitres (1,140,280,000 gallons) the previous year, and 46,017 thousand hectolitres (1,012,374,000 gallons), the average annual production of the previous five years from 1909 to 1913 inclusive.

This shows a falling-off of 9,194 thousand hectolitres (202,268,000 gallons) from the previous year's vintage, and 2,971 thousand hectolitres (65,582,000 gallons) from the previous five years' average.

The production in Piedmont, the most important wine-growing region in North Italy, was 6,500 thousand hectolitres (148,000,000 gallons) last year as compared with 7,625 thousand hectolitres (159,830,000 gallons) in 1913, and 6,184 thousand hectolitres (136,048,000 gallons) the average of the previous five years, or 765,000 hectolitres (16,830,000 gallons less than in 1913, and 316,000 hectolitres (6,952,000 gallons) more than the average.

The principal *deficit* was in Apulia, which is one of the chief wine-producing regions in the south of Italy, which yielded only 3,350 thousand hectolitres (73,700,000 gallons) last year, as compared with 6,425 thousand hectolitres (141,350,000 gallons) in 1913, and 5,212,000 hectolitres (114,664,000 gallons), the average of the five previous years. This shows a falling-off of 3,075 thousand hectolitres (67,650,000 gallons) on the previous year, and 1,862 thousand hectolitres (40,964,000 gallons) below the average. In Sicily, the production last year was slightly more than that of 1913, and above the average of the previous five years.

THE INDUSTRIES OF BENARES.

In Benares City the only industries of importance are manufactures of brass and of cotton and silk tissues. There are over six hundred brass factories in the city, the larger concerns employing twenty or more men. The skilled artisans command high wages, and are paid according to the amount of work done. The raw material is generally imported and the alloys made on the spot; the best makers preserve the secret of the proportions of copper, zinc, and other metals used to produce brass, and also of the fluxes, colouring matter, and solders employed. Water receptacles, candlesticks, and articles for religious use, temple and house decoration, and personal adornment are the chief products. The distinctive feature of Benares brasswork is its rich golden hue. There are many goldsmiths and silversmiths in Benares who turn out silverware and jewellery of a fair order. There has lately been much imitation of jewellery in brass and German silver. The demand for these articles is chiefly local, especially among women pilgrims.

About 25,000 people are employed in the cotton and silk textile industries. The output consists chiefly of the coarser kinds of cotton cloths or muslins, either plain or adorned with stripes and floral pattern, and of silk fabrics comprising every variety of silk except velvet, and ranging from the very coarse and undyed to the most elaborate brocades. These latter are widely known, and are sent not only to all parts of India, but also to Europe and America. They assume an infinite diversity of form and pattern, but the groundwork is invariably of strong silk, three to seven layers of warp threads being laid down. Sometimes this is entirely hidden by a second groundwork of gold or silver thread, over which is worked a floral or other pattern.

If the pattern be omitted, the result is plain cloth of gold or silver; but in simpler specimens the silk groundwork is allowed to appear, the pattern being woven in gold or silver thread, sometimes combined with silks of various colours. These patterns are often geometrical, but in other cases a floral design is selected, the effect in the more elaborate pieces closely resembling embroidery. These fabrics are very heavy in texture and are seldom used for garments. There is a considerable output of plain and flowered silks of all degrees of fineness. Many native garments never pass through the hands of a tailor, but are woven in the form in which they are to be worn

There is also a considerable manufacture of fancy borders, usually done in bright floral patterns, for attaching to garments and caps in place of the border woven in the same piece.

Besides articles in pure silk, the looms of Benares are noted for the production of mixtures of wool and cotton, chiefly for the use of orthodox Mohammedans, who are forbidden to wear garments of silk alone. The best known is styled *Mashru*, meaning "permitted." Closely connected with silk-weaving is embroidering, partly in silk, but more commonly in gold or silver thread. About 2,000 persons are engaged in the manufacture of gold and silver thread fabrics. The genuine thread is made from pure silver, a thin bar being passed in succession through smaller and smaller holes in an iron plate until it is only one-twelfth of an inch in thickness. It is then drawn into fine wire by a wheel-and-axle apparatus, and finally flattened with a light hammer before being wound spirally round a strong silk thread. Gold thread is obtained by coating the wire with gold as it undergoes the final process of extension. Such thread is, however, used only for the best work. Adulteration by copper or even lead is frequently practised, while turmeric is often used to impart a brilliant colour to a thin coating of gold. In some cases, too, foreign thread of inferior quality, for the most part imported from Russia, is employed, but this is never used for the highest grades of weaving or embroidery. A more recent innovation is the growing importation of high-class gold thread from France, especially from Lyons. In connection with the embroidering and tailoring trades at Benares, American sewing-machines are now very largely used.

ENGINEERING NOTES.

Aeroplaning Progress in 1914.—The year 1914 was the year of the air, as none before, since Wilbur and Orville Wright first flew. The leading features are so well described in the *Times* Engineering Supplement that perhaps one may be pardoned for quoting the passage. "It was the year wherein the world and England first saw inverted flying, looping the loop, and the 'tail slide,' or backward flying; the year of the Army's inherently stable designs in Britain; the year of the first twenty-four (and reputed thirty-four) hours' flight in Germany; the year when flight was currently undertaken against winds in which no sailing yachts can venture forth; the year of flights in seventy-mile-an-hour winds by fliers who do not pretend to be 'star pilots'; the year when heights of five miles, measured vertically, were scaled or closely approached by both French and Germans; the year when a British single-seater biplane exceeded all previous speeds of travel with 135 miles an hour air speed; the year when the factor of safety of certain aeroplanes was put up to eight times the load of ordinary flight. During the year by far the fastest stable biplane for its power, the BE, was adopted in large quantities by the Army and ordered from ten or a dozen large engineering firms, while many more have been adopted by the Navy. It was in 1914 that no fewer than nineteen persons flew together in one huge aeroplane of Russian make, some four of which are reported in use in Poland. Such a list as the above of aeronautical events and of changes effected in twelve months comes as an astonishment even to those who are immersed in the subject. For example, few are aware that an Army-built stable aeroplane has climbed into the heavens at the rate of 1,700 ft. in a minute—a rate of ascent four times as fast as an express lift in an American hotel. Again, while we have deplored the accidents to our fliers, it is not widely known that the number of accidents in Britain last year was quite trivial compared to the number in Germany, where it was reported that over three months in the spring the fatal accidents averaged one a day. Our impression of a year's interval in retrospect is largely based on the number of occurrences it contains, because such events give a long perspective, which dies away into the haze of things forgotten. From the fewness of dramatic incidents, such as fatal accidents, the aeronautical year shows, perhaps, no great vista or perspective; by the multitude of advances achieved and discoveries published, on the contrary, a great deal of history has been made."

The First Locomotive.—The first public railway opened was the Stockton and Darlington in 1825. It was the beginning of the line afterwards called the North-Eastern Railway, and in this connection a book has just been published entitled "The North-Eastern Railway," by W. W. Tomlinson. From this and other sources an outline history may be gathered. Going back to the origin of the locomotive, Solomon de Caus, a Frenchman, in 1641 proposed working carriages by steam, and so worried the authorities of the day that they shut him up in a madhouse, so that the lunacy of one century became the good sense of another. Savery later, James Watt in 1759 and again in 1784, Cuguot in France in 1763, Moore in 1769, Evans in America in 1773, Murdoch in 1784, Symington in 1786—all were feeling their way to a workable locomotive, but without success. Meantime rails had been introduced for horse-drawn vehicles, and Richard Trevethick, who was the real father of the locomotive which could draw a load, exhibited one in London on rails in 1808. It must be remembered that the idea of making an engine go by forcing its wheels round, as in the present-day locomotive and motor-car, was quite unfamiliar to the men of that time; thus it was that the cogwheel was tried by Blenkinsop, but it was found that the same result could be achieved by adding weight, and so gaining the necessary adhesion. In 1825 Timothy Hackworth's locomotive of 6½ tons for the Stockton and Darlington Railway, and George Stephenson's "Rocket" for the Liverpool and Manchester, where success was

finally attained in 1830, were constructed. It is a far cry to the 380-ton triplex cylinder Mallett engine on the Erie Railway of to-day. Outside the invention of printing, there is no mechanical revolution approaching this.

The Hutson Ford Turbine.—This turbine was described by Mr. E. Hutson before the Junior Institution of Engineers. The steam enters through a kind of slide-valve having an expanded nozzle, passes through the blades on the rotor, and leaves by a port on the opposite side of the casing. The centre line of the steam and exhaust ports is a tangent to the rotor, so that the high-velocity steam travels across the rotor in as nearly a straight line as possible. After leaving the exhaust of the first stage the steam is conducted to a second stage rotor of greater area, and so on till the final exhaust is reached. A number of nozzles are in action at the same time. The rotor blading is composed of two alternate zigzag forms, one having steeper angles than the other, so that a succession of alternating and expanding contracting channels is formed. These blades are pressed out in the form of a ring and slipped on the rotor-drum a row at a time. The guide-blades form, in conjunction with the working blades, a series of expanding nozzles, which increase the velocity of the steam after it has impinged on the working blades, the steam thus giving a succession of impulses to the rotor from the inlet to the exhaust. These guide-blades are fixed to the rotor and revolve with it, so that the steam pressure on them, as well as on the working blades, is transferred to the shaft. To change the direction of rotation a wheel is turned which reverses the steam and exhaust ports, whereby the direction of the flow of the steam through the blades is reversed. The report comes from the *Times*.

Birmingham Power-plant.—We learn from *Electrical Engineering* that the Birmingham Corporation has decided to put down a temporary generating station to deal with the enormous number of applications for electric power that are coming in, mainly from manufacturers of war material, pending the completion of a large new station at Nechells. The present plant will be sufficient for this winter, and the temporary station is to provide for the winter load of 1915–16. The permanent Nechells station is expected to be ready for the winter of 1916–17. The temporary plant will be of 10,000 kilowatts capacity, and will be put upon a site adjoining the Nechells works in a way that will not interrupt the contracts now in hand. The estimated cost of the plant amounts in all to £97,000. The following plant has been already ordered: six marine type water-tube boilers, from Babcock and Wilcox, Limited; two 5,000-kilowatt turbo alternators, with condensers, from the British Westinghouse Electric and Manufacturing Company, Limited; and five cooling towers from the Davenport Engineering Company. The rest of the plant for which contracts are to be placed comprises coal conveyers, feed-pipes, piping and valves, switch-gear, cables, etc. The cost of temporary foundations and buildings is estimated at about £10,000; but all the plant with this exception will be incorporated into the Nechells station when the plant therein is sufficiently advanced to permit of its being released. In view of the extreme urgency, the work is being proceeded with in anticipation of the sanction of the Local Government Board to the necessary loan.

The Malleable Iron Industry.—This dates from a patent obtained in 1804 by an Englishman, Samuel Lucas. In the United States, Seth Boyden first made malleable castings in Newark, New Jersey, in 1826. About two hundred and fifty firms in this country now produce malleable castings, the total output being about 1,000,000 tons per year. The industry is almost exclusively an American one, malleable iron being made in Europe only on a very limited scale. The most rapid growth in the industry has occurred during the past twenty years. In that time malleable iron has almost entirely replaced cast iron in freight-car construction and in agricultural manufacture. A good malleable iron should have a tensile strength of 35,000 lbs. to 55,000 lbs., or even 60,000 lbs. per square inch, with an elongation 3 per cent. to 8 per cent. in two inches. The above statements are taken from a paper on malleable iron read recently by J. P. Pero at the Chicago meeting of the American Foundrymen's Association. Mr. Pero further says: "Its greatest advantage is the fact that the metal is not subject to crystallisation or fatigue, but will stand as severe a test after twenty or twenty-five years of use as it will when originally made, no matter how great the vibration may have been to which it has been subjected. If proper care is used in its manufacture, it should be quite free from internal flaws, such as blow-holes or shrinkage flaws, while it will stand considerable abuse and distortion before breaking, is much more rigid, and will resist the tendency to become distorted to a greater extent than either drop forgings or steel castings of the same sections. Malleable iron also resists rusting or corrosion very much better than either wrought iron or steel, running only slightly below cast iron in its resisting qualities to oxidation."

CORRESPONDENCE.

THE DECORATIVE TEXTILE INDUSTRIES AND THE DESIGNER'S RELATION THERETO.

In my paper on the Decorative Textile Industries I somewhat severely criticised the Schools of Art, and I should have been much surprised if this criticism had passed unchallenged. Indeed, I was hoping it would not, that I might have a better opportunity of demonstrating their weakness.

I therefore have to thank Mr. Chas. A. Eva for his letter which gives me this opportunity. In entering the lists he has been rather unfortunate in his selection of Mr. Frank Warner as a champion of his cause. This gentleman has been working for many years past in attempts to reform these schools, and whatever isolated quotations may be taken from his various addresses they are surely negatived by such a remark as "I am reluctantly compelled to admit that Art training in design stands out to-day as our weakest spot." He and the departmental committee of inquiry into the functions and practical working of the Royal College of Arts made an unqualified condemnation of this institution. This was in 1910, but still it goes on its way entrenched behind vested interests and Government officialdom, entirely indifferent to our industrial economy and the British taxpayer's purse.

May I give my own experience of this institution as an instance of its futility as a training ground for Art industry? Some three years ago I was in need of an efficient assistant, and made application at the College. I was interviewed by the design master, a professional architect, and he assured me that he had several National scholars who had finished their course of study and who would meet my need in every possible way, but what salary was I prepared to give? I said I was prepared to give £5 per week to a competent man, and was duly supplied with a young fellow who commended himself to me as having, before gaining his scholarship, served some apprenticeship in the studio or "drawing shop" of a Manchester printer. It did not take me long to discover that his artistic and technical knowledge of cotton printing had lain fallow during his college days, indeed interest and ability in this direction, rather than being developed, had become obscured by all the varied and perfunctory studies of other industrial arts and crafts. Needless to say I could not keep this man at £5 per week, and in discharging him, after a month's trial, I wrote to the headmaster to the effect that he could have little knowledge of my requirements, and much less of the commercial value of his trained students.

This particular instance is one of many that are coming to my notice from other people who have tried to employ these National scholars.

I am convinced that an academic institution such as this should not undertake to supply Art industry with well-paid workers in any branch of it.

Mr. Eva commences his letter by saying that "The aim of the Schools of Art is to provide a sound basis for all branches of Art." My reply to this is that it is impossible under the Schools' present government to provide a sound basis for *all* branches. It would be absurd to expect it, leaving outside the influence of fashion and the "latest craze." How is it possible for a master of design outside trade, and bred of a race of teachers, to attempt to inculcate anything more than his limited knowledge? It would be presumption for the Board of Education or any municipal council to expect to find a teacher well equipped in the requirements of his particular industry to give his services for the remuneration that is usually given to the Art teacher. We cannot expect it. But employers of artistic labour ought surely to be able to look to the schools for a supply of efficient draughtsmen "on tap," as Mr. Eva so cleverly puts it.

I detect also in his remarks an insinuation that an employer like myself is only out for cheap and journeyman labour. He asks: "After these students have been tapped, what will become of them?" He also asserts "that those students who supply textile producers with sketch designs at twenty shillings each, probably make more money than they would in a design studio." Both question and assertion are the result of a refusal to consider what I had been at some pains to point out in my paper. While disparaging the efforts of those who attempt the difficult task of organising labour in a studio, he says that the need is for *more* studios to which, as in Paris, the student can go with more certainty of employment.

I would ask him to read my paper with a little more care, and so dispel the notion that the facts I quoted about German designs are misleading. He must, moreover, give me credit for a full appreciation of what the Schools of Art have done towards a better knowledge of Art. This is unquestionable. To confuse my candid and practical criticism with anything like an abuse of the schools and the Art master shows a lack of discrimination. This coming from an Art master confirms me in the belief that the Schools of Art are employing men out of sympathy with any effort to bring about a better understanding between trade and Art, and that the students under their guidance are being taught to discredit the trade that is to provide them with a livelihood.

To those designers who have been labouring for years in intimate association with trade, trying to better the difficult conditions that exist for all artists concerned, it is discouraging to find those who will not lift a finger to help to protect from utter annihilation what Art there already exists in industry. We who are still fighting for the just claims of the artist have a right to expect the support and help of our Art Schools and masters, and the students have a right to look for employment in efficient trade studios, where their efforts will not be scattered and dissipated. It is a well-known fact, of which Mr. Eva has full cognisance, that apprentices employed in trade studios are invariably those students who gain the prizes for pattern design in the Schools of Art. Let me here give the reason. Apart from their designs being more technically practicable, they have learnt how to draw with refinement and precision. In other words, they are workmen who know their job.

Until, therefore, the Schools of Art will insist on a much higher standard of excellence in draughtsmanship and drop the idea of "providing a sound

basis for all branches of Art," they will remain discredited by industries calling for the specialised worker. To effect this end our Schools want entire reorganisation, and, as insisted upon in my paper, a more potent centralisation of certain and specific industries in whatever districts they can serve best. The principals must make it a *sine quâ non* with all students who enter for training that they remain a full term of years, so preventing the "half-baked" production that is now exhausting the patience of industry by his incompetency.

ARTHUR WILCOCK.

With reference to the Schools of Art as a source of design supply for the decorative textile trades, may I, as a representative of Messrs. Story & Co., give expression to one or two points which I feel may help, in some small measure, to push on toward realisation, a point, I took it, which Mr. Arthur Wilcock wished to convey in his lecture last week?

As buyer for a firm who have done a good deal in the way of producing printed and woven fabrics, I do find that the quality of designs, as turned out by students from the Art Schools, leaves very much to be desired, and, though admitting that in many cases we get originality, the lack of technical education makes it imperative on the producer to hand the design over to a practical designer to re-do, or to make it sufficiently clear for the printer to work from.

I think if some organised efforts were made whereby the student could, before launching these unfinished designs on the market, get the finished technique of the designs of some of our organised studios in London, and also of the Paris designers, it would raise the standard of work and save many a student from falling out from what ought to be a lucrative vocation.

There ought to be, in my opinion, some teacher at each school who has made himself cognisant of what the printers' possibilities are, and by this I mean has obtained some practical knowledge by a course of actual study at some well-known print works, and also visited the London and Paris retail houses with a view to seeing the latest productions and to becoming acquainted with all the novel effects which are annually sprung on the market.

As one who annually visits Paris for designs and sees the wonderful collection the Frenchmen get together, as compared with the few designs most of our English artists show, I can only feel what a big thing might result by some organised effort. It must be admitted that the average artist finds the commercial part of the business irksome. Therefore I think if he could be helped by some of his more commercial artist friends, we should thus keep in our own country much of the trade for which our Continental producers find England a good market. We have plenty of good talent stranded for lack of organisation.

R. H. GARTON.

I fear that my views regarding the practical value of the student trained at the Art Schools of this country will not be pleasing to the gentlemen responsible for the management of these institutions. I give my opinions from the point of view of the producer, and from the commercial, and also, I think, a little from the artistic standpoint. The last of these points of view, however, is possibly of no value in this discussion.

I have always made it a rule, up to the present, to examine carefully all designs that are brought to me, and this rule I have faithfully carried out, and I have found it a wise thing to do. There is, however, one class of designer that comes to me whose work I am forced now to consider an absolute waste of time to examine, and that class is the student trained at the Art Schools. I speak from experience, as I have carefully examined many hundreds of drawings made by these students, and I can truthfully say that I have never once found a single design that contained, in my opinion, any commercial utility or artistic ability. It appears to me that the fault lies in the fact that the students are almost incapable of drawing from Nature; they can, no doubt, copy a vase or similar object, but cannot draw a rose or other flower truthfully.

This fact appears to me to limit them to the modern Continental design, which type is of no commercial value at the present moment in the print trade. It seems to me a great pity that this situation is allowed to continue, as it should be an easy matter to alter. I have also noticed an absence of practical knowledge regarding the sizes of blocks and rollers, and the general method of drawing up designs for prints in such a form that they are intelligible to a blockcutter or practical printer.

I am very sorry to have to offer such a poor opinion of the Art Schools' students from a producer's standpoint, but I can only put things as I find them.

I only hope that I have been unlucky in not seeing the best students, but since so many people call on me with designs, I fear this is not the case.

ERIC NEWMAN
(Of Messrs. Newman, Smith & Newman).

OBITUARY.

BERNARD LE NEVE FOSTER, J.P.—Mr. Bernard Le Neve Foster, who died suddenly on February 21st, was the seventh of the eight sons of Peter Le Neve Foster, who was Secretary of the Society of Arts from 1853 to 1879. He was born in 1851. He was for many years a director of the well-known firm of Lincoln, Bennett & Co., the hat manufacturers, and he took a great deal of interest in that industry. He resided for many years at Sennowe Hall in Norfolk, where he made some experiments in pisciculture, a matter to which he had devoted considerable attention. He also

experimented with the cultivation of sugar beet, and in other agricultural matters. Latterly he resided at Dormans Park in Surrey. He married in 1888 Emma Elizabeth, daughter of the late John Fletcher Bennett, of the above firm. She died in 1895, leaving a family of one son and one daughter. Mr. Bernard Le Neve Foster became a member of the Society in 1880.

NOTES ON BOOKS

SVA. By Sir George Birdwood, K.C.I.E. Edited by F. H. Brown. London: Lee Warner. 1915. 12*s.* 6*d.*

Sir George Birdwood's friends—and they are very numerous—will welcome this collection of his miscellaneous writings, with its enigmatical title. Sva, however, is no word of mystic import, of thaumaturgic or occult power, but merely an etymological variant of *sua*, and implies nothing more recondite than that the author has here brought together specimens of his "very own," the writings we may take it on which he sets most store, and by which he will prefer to be judged.

Many of the articles here reprinted will be familiar to readers of the *Journal*, for a large proportion of them have appeared, in one form or another, in its pages. They all possess the quaint charm of the writer's personality, the queer "conceited" phraseology in which surely no one since Lyly, the Euphuist, has ever so much delighted; the love of pursuing a word or an idea through half a dozen tongues and twice as many writers; the tracing out of queer etymologies, often with a joyous disregard of orthodoxy and convention; the stores of curious lore gathered from Western or Eastern sources indifferently. These, and half a dozen other idiosyncracies, give Sir George Birdwood's writings a character entirely peculiar to themselves, and, when the author is content not to allow too free a rein to his caprices, lend a special charm to his treatment of subjects in themselves often technical and unattractive.

The only new contribution to the present volume is the preface, in which, after certain ambagious divagations, Sir George sets out clearly and shrewdly the views about India which he has been preaching now, may we say, for about half a century. Few men, probably, know India in the sort of way he does. He has falsified Rudyard Kipling's statement about East and West, for the two seem not only to have met, but to have been incorporated into a single personality. Though he was born in India, and was an Indian official for many years, probably the length of his service is a good deal less than that of many Anglo-Indians. But he seems to have acquired an intuitive knowledge of the Indian native, to be able to realise his point of view, to know what he thinks, to appreciate his wishes and his feelings in a way that only a few exceptionally gifted servants of the Company or the Crown have ever equalled. This makes whatever he has to say on a subject of Indian policy of special value. He may be wrong, like most of us, but at all events he can give us a view of Indian questions which does not of necessity present itself to Indian administrators, however able, however experienced.

Of course Sir George Birdwood is paradoxical in stating his views—your true Euphuist loves nothing so well as a paradox. He will not admit that we are bound, in governing India, "to seek any other end therein than the satisfaction of our own covetous and grasping needs." That presumably is the view of the Western half of his duplex personality. The Eastern half is of quite a different opinion, and "of religious inspiration" is convinced that it is incumbent on the ruling race "to subserve her material and moral advantage." When, however, it comes to the question of how the result is to be attained, East and West are in accord. Western induction and Eastern intuition lead for once to the same conclusion, and one in which many will sympathise if they hesitate definitely to agree with it. So far as one dare condense Sir George's eloquent periods, it appears to be certain that he attributes our failures—where we have failed—to the constant effort to develop Indian institutions in accordance with European ideas, instead of on Eastern models. In education, in art, in manufacture, in religion, it is always the same. We "impose our European culture upon them, not as a supplementary accomplishment, but in supersession of their own traditional learning, literatures, arts and religions." The students we have educated are only fit for Government clerks, the artists are taught to copy European methods and to neglect their hereditary styles, the manufacturers and the farmers are induced to substitute Western machines and implements for the tools and appliances sanctified by tradition, while the most religious peoples of the earth are being turned into atheists.

It is possible that our author might hardly recognise his views, thus crudely stated. Yet this is really a not unfair rendering of opinions which are held by many educated Indians, by many who know India. And in Sir George Birdwood's case, they are, in bald abstract, the ideas of a man of the widest sympathy and of the kindest nature, no friend of national congresses and popular agitations, but a man who knows and loves India and its people as few know and love them. None, too, knows better or has said more plainly that they are applicable only to a minute fraction of the huge population of India, with its numerous nationalities differing in race, customs, manners, religion and character as do the various peoples of Europe.

How the great problem of the administration of India by England will eventually be solved it is idle to try to guess, but it is quite certain that the life-work of George Birdwood has done something for its solution, and that the writings in which he has endeavoured to state at least a portion of the experience he has accumulated will do even more to help it after he has passed away.

GENERAL NOTES.

THE IMPERIAL INSTITUTE. — The annual report on the work of the Imperial Institute for 1913 shows that a large number of scientific, technical, and commercial investigations as to the composition and value of raw materials were conducted during the year. The number of reports completed in 1913 was four hundred and sixty, and at the close of the year one hundred and twenty-four investigations were in progress. Inquiries were received from nearly fifty different countries, while a large number also came from commercial firms in the United Kingdom. The work of collecting and collating the information necessary to answer these inquiries is severely taxing the staff of investigators attached to the department, and it is hoped that a separate staff, constituting a technical information bureau, may be established shortly.

SIR WILLIAM WHITE MEMORIAL FUND.—The appeal for subscriptions to this fund has resulted in a sum of £3,076 14*s.* 6*d.* having been contributed to date by four hundred and fifty-five subscribers. The committee, after carefully considering various suggestions, have decided that the most suitable form which the memorial could take would be the establishment of a research scholarship in naval architecture to be named after Sir William White, and they have accordingly arranged to hand over to the council of the Institution of Naval Architects the greater part of the funds subscribed, so that a sum of at least £100 a year shall be available for the scholarship, which will be administered by the council of that Institution. As a number of subscribers, more particularly those representing engineering societies in America and on the Continent, were anxious that their donations should be devoted to some form of memorial tablet, it has been arranged for a medallion portrait to be placed, by the kind permission of the Institution of Civil Engineers, in their handsome new building. Finally, at the suggestion of Lady White, a donation of one hundred guineas has been made to the Westminster Hospital, where Sir William White passed away. Any surplus left over after defraying the cost of the memorial tablet, the donation to the hospital, and the small charges incidental to printing and postage, will be devoted to increasing the value of the research scholarship. Additional donations can therefore still be received for that purpose.

THE TIMBER RESOURCES OF CUBA.—The forest areas of the island are mainly in the Santiago district, and although during the last decade immense areas have been cleared for cultivation, it is estimated that about one-seventh of the cultivable area of Camaguey and Oriente Provinces yet remains in primeval forests. While undoubtedly there still exists in the Cuban forests much valuable timber, they have been depleted to a great extent of those valuable woods for which there is a demand in foreign markets, especially cedar and mahogany. The Government exercises control over the forests, whether of public or private ownership, and no timber can be cut for any purpose without a permit being obtained from the chief of the Bureau of Forestry of the district in which the timber is situated. Notwithstanding the stringent laws and regulations adopted to prevent the cutting of timber on lands by persons who have no right thereto, the forests on lands belonging to the State have been robbed and in a great measure stripped of their most valuable products. Much of the land classified as forest or timberland has long since been stripped of all timber of marketable value, and at the present rate, with no effort at renewal, it will not be long until no merchantable timber will be found in the island.

THE STRAW BRAID AND STRAW HAT INDUSTRY IN CHINA.—About 6,000 tons of straw braid go from Shantung each year to foreign countries for manufacture into straw hats. The straw braid is made of wheat straw, and hence can only be produced in those parts of China growing wheat, which means the north, or, rather, that district north of the Yangtze River. Even in the wheat-growing districts there are only certain parts which produce straw braid. For instance, in Shantung Province, although wheat is grown in most districts, the production of straw braid is confined to one or two places only. The best braid is produced in the Shaho district, north of Weihsien, on the Shantung Railway. The visitor to the Shaho district at any time when the wheat is being harvested, would find the entire population engaged in stripping, cutting, or plaiting straw for straw braid. Only that part of the straw above a foot from the root can be used for braid. Pieces five and six inches in length are thus secured, cut lengthwise into a number of strips, and then dampened and plaited. The better qualities are used for first-grade braid. Brokers buy the plaited braid for shipment to Tsingtau for the foreign exporters. Labour is so cheap in China that it will probably not be many years before the bleaching, now done in England, and in normal times in Germany, will be undertaken in China, and the straw hats manufactured there at a fraction of the present foreign cost.

LORD ROBERTS MEMORIAL FUND.—In view of the wide interest which has recently been exhibited as to the future of the partially disabled sailor and soldier, an appeal is being made for the necessary funds for a considerable extension of the workshops of the Incorporated Soldiers and Sailors Help Society. In these workshops, men who have been partially disabled on active service are taught various trades, such as basket making, carpentering, carving, gilding, polishing, framing, metalwork, and electric fitting; and ten years' experience since the South African War has

convinced the committee that their scheme is the most practical one available for benefiting these men, not only pecuniarily, but also morally and physically, by keeping their minds and bodies regularly employed. Up to now, owing to lack of funds, it has only been possible to deal with this problem on a comparatively small scale; but in view of the very large number of such cases now being referred to the Society, and obviously greatly on the increase, they are convinced that they have only to lay their appeal before the public to ensure an immediate response. It is their hope that, given the necessary funds for working expenses, they will be able to obtain more commodious workshops in different localities, and by working with modern machinery, instead of entirely by hand, they will be able to create a much larger market for the men's goods than hitherto. Experience shows that for every £100 received they will be able to take in a disabled man, and to pay him an average wage of £1 per week for the first year, and £1 5s. per week afterwards. The committee also have the authority of the family of the late Lord Roberts for saying that they would welcome the proposed extension of the workshops as a memorial to the great Field-Marshal, the Countess Roberts being of opinion that he himself would have desired no greater memorial than this provision for disabled men, by means of a practical scheme in which he always took so great an interest. The Right Hon. Sir Frederick Milner, Bt., has consented to act as hon. treasurer of this Memorial Fund, and donations may be sent to him at 122, Brompton Road, S.W.; to H.R.H. Princess Christian, at Schomberg House, Pall Mall, or to Major-General Lord Cheylesmore, at 16, Princes Gate, S.W.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock (except where otherwise announced):—

March 10.—J. W. Gordon, K.C., "Patent Law Reform and the War." Dugald Clerk, D.Sc., F.R.S., will preside.

March 17. — H. M. Thornton, "The Industrial Uses of Coal Gas." Sir Corbett Woodall, D.Sc., M.Inst.C.E., Governor of the Gas Light and Coke Company, will preside.

March 24, at 4.30 p.m.—Lady Lugard, "The Work of the War Refugees' Committee." Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, will preside.

April 14. — T. Thorne Baker, "The Industrial Uses of Radium."

April 21.—Moreton Frewen, "Profit and Loss in Our Sea Fisheries."

Indian Section.

Thursday afternoons:—

March 18, at 4.30 p.m. — Lieut.-Colonel A. C. Yate, I.A. (retired), "The Indian Army." The Right Hon. Viscount Bryce, O.M., D.C.L., LL.D., F.R.S., will preside.

April 15, at 5 p.m. — Perceval Landon, "Basra and the Shatt-ul-Arab." The Right Hon. Earl Curzon of Kedleston, G.C.S.I., G.C.I.E., will preside.

May 13, at 4.30 p.m.—M. M. S. Gubbay, I.C.S., "Indian Trade and the War."

Colonial Section.

Tuesday afternoon, at 4.30 o'clock:—

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials."

Dates to be hereafter announced: –

C. H. Sherrill, "Ancient Stained Glass."

A. S. E. Ackermann, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., "On an Economical and Smokeless Grate, and on the Measurement of the Efficiency of Open Grates."

Aldred Lecture.

Thursday afternoon, at 4.30 o'clock:—

March 11.—M. Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "L'évolution de l'école Belge de Peinture (1830–1900)." Lord Sanderson, G.C.B., K.C.M.G., Vice-President of the Society, will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

M. H. Baillie Scott, "House Building: Past and Present." Three Lectures.

Syllabus.

Lecture I.—March 15.—*House Building, Past and Present.* The nature of the building art—The modern conception of building and architecture—The utilitarian spirit in house building—The house necessarily a work of art, good or bad—As such has degenerated in modern times—The old house still the best—Architecture a dangerous term, and why—No art is degraded because it is useful—The

fallacy of pure art—No pure art in nature—Art must cling to life and express itself in the service of life.

LECTURE II.—MARCH 22.—*Houses in the Past in this Country*. Three main periods: (1) The craftsman or mediæval period, when the art of building flourished; (2) The scholar, or Renaissance period, when the building art became "tongue-tied by authority"; (3) The shopkeeper, or commercial period—The distinguishing features of the three periods set forth as an allegory—The trades guilds—The spirit and methods of the old craftsmen—The scholar spirit—The commercial spirit.

LECTURE III. — MARCH 29. — *Houses of the Present*. The average house of the craftsman period adorned the world—The average modern house disfigures the world—Normal modern building a disease rather than an art—The causes and cure of this disease—Difficulties of the architect—Building by-laws—The qualities of various types of houses discussed—An ideal house described.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.
April 26, May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 8...African Society, Hotel Cecil, Strand, W.C., 8 p.m. M. Emile Vandervelde, "Belgian and British Interests in Africa."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Sir D. M. Hamilton, "India after the War from the Economic Standpoint."

Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. A. R. Ling, "A Review of our Knowledge of the Changes which occur in the Fermenting Vessel, Storage Vat, and Cask."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Discussion on papers by Messrs. J. Dixon and E. H. N. Ryde, "The Report of the Land Inquiry Committee on Rating."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Professor S. Gardiner, "Our Fisheries and their Geography."

Engineers, Cleveland Institution of, Middlesbrough, 7.30 p.m.

TUESDAY, MARCH 9...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Mr. S. H. Swinny, "An Historic Interpretation of the War."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Mr. F. Legge, "The Worship of Mithras and its Mysteries."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. J. Pope, "Colour Photography—Scientific Applications." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. Sir T. Mason, "The Improvement of the River Clyde and Harbour of Glasgow, 1873-1914."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. R. G. Barker, "A Comparison between Simple and Elaborate Schemes of Colour for Domestic Decoration."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Messrs. A. J. Bull and A. C. Jolley, "On the Character of Selective Absorption."

Pharmaceutical Society, 17, Bloomsbury-square, W.C., 8 p.m. Dr. F. Hooper, "Trees that Weep: a Study of the Natural Exudations of Plants."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. C. P. Sparks, "Electricity applied to Mining."

(Scottish Section.) Princes-street Station Hotel, Edinburgh, 8 p.m. Mr. E. B. Wedmore, "Automatic Protective Switchgear for Alternating-Current Systems."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 8 p.m. Discussion on "Maternity and Child Welfare Schemes."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Mr. F. F. Laidlaw, "Contributions to a Study of the Dragonfly Fauna of Borneo." 2. Messrs. G. Arnold and C. L. Boulenger, "On a Freshwater Medusa from the Limpopo River-System"; and other papers.

WEDNESDAY, MARCH 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. G. Gordon, "Patent Law Reform and the War."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. F. W. Lanchester, "The Flying Machine—the Aerofoil in the light of Theory and Experiment."

Electrical Engineers, Institution of (Yorkshire Section), Philosophical Hall, Leeds, 7 p.m. Mr. W. R. Cooper, "Electric Cooking, mainly from the Consumer's Point of View."

Geological Society, Burlington House, W., 7.45 p.m. Special General Meeting.
8 p.m. 1. Mr. C. Reid, "The Plants of the Late Glacial Deposits of the Lea Valley." 2. Mr. S. Smith, "The Genus *Lonsdaleia* and *Dibunophyllum rugosum* (McCoy)."

THURSDAY, MARCH 11...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Aldred Lecture.) M. Paul Lambotte, "L'évolution de l'école Belge de Peinture (1830–1900)."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 7.30 p.m. Discussion on "The Care and Development of the Child during School Age."

Royal Institution, Albemarle-street, W., 3 p.m. Sir H. Warren, "Poetry and War." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. S. G. Gamble, "The Campaign against Fire."

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. Mr. R. S. Whipple, "Instruments in General Use for the Measurement of Solar Radiation."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. W. R. Cooper, "Electric Cooking, mainly from the Consumer's Point of View."

FRIDAY, MARCH 12...Chadwick Public Lecture, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Mr. A. Smith, "The War and the Wounded."

Royal Institution, Albemarle-street, W., 9 p.m. Sir R. J. Godlee, "Back to Lister."

Malacological Society, Burlington House, W., 8 p.m. 1. Messrs. A. S. Kennard and B. B. Woodward, "On *Helicella crayfordensis*, n. sp. from the Pleistocene deposits of S.E. England." 2. Rev. E. W. Bowell, "Further Notes on Radulæ." 3. Mr. A. Reynell, "On the editions of Swainson's Exotic Conchology."

Astronomical Society, Burlington House, W., 5 p.m.

Physical Society, Imperial College of Science, South Kensington, S.W., 8 p.m.

SATURDAY, MARCH 13...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Recent Researches on Atoms and Ions." (Lecture IV.)

Journal of the Royal Society of Arts.

No. 3,251. VOL. LXIII.

FRIDAY, MARCH 12, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 15th, 8 p.m. (Cantor Lecture.) M. H. BAILLIE SCOTT, "House Building: Past and Present." (Lecture I.)

WEDNESDAY, MARCH 17th, 8 p.m. (Ordinary Meeting.) HORACE MOORE THORNTON, M.I.M.E., "The Industrial Uses of Coal Gas." SIR CORBET WOODALL, D.Sc., Past President of the Institution of Gas Engineers, will preside.

THURSDAY, MARCH 18th, 4.30 p.m. (Indian Section.) LIEUT.-COLONEL A. C. YATE, I.A. (retired), "The Indian Army." The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

ALDRED LECTURE.

Thursday afternoon, March 11th; LORD SANDERSON, G.C.B., K.C.M.G., in the chair. The Aldred Lecture on "L'évolution de l'école Belge de Peinture (1830-1900)" was delivered by M. PAUL LAMBOTTE, Directeur des Beaux Arts au Ministère des Sciences et des Arts de Belgique.

The lecture will be published in a subsequent number of the *Journal.*

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1915 early in May next, and they therefore invite members of the Society to forward to the Secretary on or before Saturday, March 27th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded in previous years as follows:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measurement and uniform standards, by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb R.S., Chevalier of the Legion of Honour, etc., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I., "for services rendered to Arts, Manufactures, and Commerce by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in

aiding the establishment and development of International Exhibitions, the Department of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvements in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential services in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious manual labour."

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labour in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of our several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

In 1885, to Mr. (afterwards Sir) Henry Doulton, "in recognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham), "for the services he has rendered to the textile industries, especially by the substitution of mechanical wool combing for hand combing, and by the introduction and development of a new industry—the utilisation of waste silk."

In 1887, to Her Majesty Queen Victoria, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during the fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science, and of their practical results upon music, painting, and the useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar—a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by

the application of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as Chemist to the War Department."

In 1892, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S., "for their joint services to scientific agriculture, and notably for the researches which, throughout a period of fifty years, have been carried on by them at the Experimental Farm, Rothamsted."

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries, by which not only has the art of surgery been greatly promoted, and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required for carrying the treatment into effect."

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his metallurgical researches and the resulting development of the iron and steel industries."

In 1896, to Professor David Edward Hughes, F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone."

In 1897, to George James Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water-supply and the sewerage of towns a trustworthy basis for their work, by establishing and carrying on during nearly forty years systematic observations (now at over 3,000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S., "in recognition of his numerous and most valuable applications of Chemistry and Physics to the Arts and to Manufactures."

In 1899, to Sir William Crookes, O.M., F.R.S., "for his extensive and laborious researches in chemistry and in physics—researches which have, in many instances, developed into useful practical applications in the Arts and Manufactures."

In 1900, to Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small—a discovery now used in all dynamo machines—and for its application to the production of the electric searchlight, and to the electro-deposition of metals from their solutions."

In 1901, to His Majesty King Edward VII., "in recognition of the aid rendered by His Majesty to Arts, Manufactures, and Commerce during thirty-eight years' Presidency of the Society of Arts, by undertaking the direction of important exhibitions in this country, and the executive control of British representation at International Exhibitions abroad, and also by many other services to the cause of British Industry."

In 1902, to Professor Alexander Graham Bell, "for his invention of the telephone."

In 1903, to Sir Charles Augustus Hartley, K.C.M.G., "in recognition of his services, extending over forty-four years, as Engineer to the International Commission of the Danube, which have resulted in the opening up of the navigation of that river to ships of all nations, and of his similar services, extending over twenty years, as British Commissioner on the International Technical Commission of the Suez Canal."

In 1904, to Walter Crane, "in recognition of the services he has rendered to Art and Industry by awakening popular interest in Decorative Art and Craftsmanship, and by promoting the recognition of English Art in the form most material to the commercial prosperity of the country."

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S., "in recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S., "for the important part he took in the invention of the incandescent electric lamp, and for his invention of the carbon process of photographic printing."

In 1907, to the Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E., "in recognition of his pre-eminent public services in Egypt, where he has imparted security to the relations of this country with the East, has established justice, restored order and prosperity, and, by the initiation of great works, has opened up new fields for enterprise."

In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S., "for his investigations into the liquefaction of gases and the properties of matter at low temperatures—investigations which have resulted in the production of the lowest temperatures yet reached, the use of vacuum vessels for thermal isolation, and the application of cooled charcoal to the separation of gaseous mixtures and to the production of high vacua."

In 1909, to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S., "in recognition of his long-

continued and valuable researches into the nature and action of explosives, which have resulted in the great development and improvement of modern ordnance."

In 1910, to Madame Curie, "for the discovery of radium."

In 1911, to the Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S., "for his experimental researches into the laws governing the efficient action of steam in engines of the turbine type, and for his invention of the re-action type of steam turbine, and its practical application to the generation of electricity and other purposes."

In 1912, to the Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S., "for his services in improving the railway communications, developing the resources, and promoting the commerce and industry of Canada and other parts of the British Empire."

In 1913, to His Majesty King George V., "in respectful recognition of His Majesty's untiring efforts to make himself personally acquainted with the social and economical conditions of the various parts of his Dominions, and to promote the progress of the Arts, Manufactures, and Commerce in the United Kingdom and throughout the British Empire."

In 1914, to Chevalier Guglielmo Marconi, LL.D., D.Sc., "for his services in the development and practical application of wireless telegraphy."

PROCEEDINGS OF THE SOCIETY.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 10th, 1915; Dugald Clerk, D.Sc., F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Baltimore, Professor Jeremiah D., Armstrong Technical High School, Washington, D.C., U.S.A.

Murphy, Joseph Plato, Zorgenhoop, West Bank, Berbice, British Guiana.

The following candidates were balloted for and duly elected Fellows of the Society:—

Kerr, Harry Roe, care of Messrs. Steel Bros. & Co., Ltd., P.O. Box 132, Rangoon, Burma.

Nuttall, Walter Harold, F.I.C., F.C.S., The Cooper Laboratory of Economic Research, Watford, Herts.

The paper read was—

PATENT LAW REFORM.

By John William Gordon, K.C.

The war which has opened our eyes to a great many obscure facts about ourselves, has also brought home to us certain facts about which there has never been any obscurity at all. Among these latter, the very evident fact that certain branches of chemical industry have been monopolised by German manufacturers has recently assumed especial interest. For it appears that this very open secret has become known to the Government, and that they propose to meet an emergency which has at the present time assumed an acute form by very heroic measures of relief. It is highly satisfactory to those of us who have been crying in the wilderness for years past, upon the subject of this and similar defects in our industrial organisation, to find that attention is being bestowed upon them in influential quarters. It is interesting, and not unimportant, perhaps, to note the theory which underlies the Government proposals as to the essential cause of our shortcoming. That theory, if I understand it aright, is that the British manufacturer is a man of short views, intellectually lethargic, a sceptic as to the practical value of technical education and scientific research, and a man to whom the pursuit of an industry involving continuous and strenuous mental activity is so uncongenial as to be impracticable. This is an interesting view of the intellectual limitations of our countrymen, and it is one which I do not propose to controvert, not even to discuss, this evening. I note it only for the purpose of taking the measure of its bearing upon the official proposals now made for dealing with the difficulties of the present situation, and, incidentally, for the purpose of satisfying this Society that it is expedient to consider in this same connection further measures than those indicated in the official programme, measures for which there will still be an urgent call, even when everything has been effected which it is possible to accomplish in the way of stimulating, instructing, and, in the full sense, waking up the sleepy and ineffective British manufacturer.

While, however, accepting this official view without cavil, it is still legitimate, on the principle of giving even the Devil his due, to recall the fact that, notwithstanding our limitations, we actually were the pioneers of technical education in the modern sense of that word. It may indeed be said, and with much probability, that our circumstances had more to do than our character with this development of our educational history. The small beginnings of technical education must be dated at the commencement of the nineteenth century, when, of all the great industrial nations of the world,

only our own was in a position to develop along those lines. The wars of the French Revolution had laid the Continent of Europe in ruins. The manufacturing industries of America were in their infancy. Russia and Japan had not yet started along the path of industrial development. The fact of British priority in this field may therefore be recorded without making any invidious claim to superiority over neighbouring peoples. Even in our own country the beginnings were small enough. The opening of the nineteenth century witnessed a great popular awakening of intellectual life in this country, of which technical education was one phase. That great movement expressed itself in the formation of numerous societies and voluntary associations of intellectually awakened people for the study of the arts and sciences. The distinctive feature of those societies was that they were non-professional and extra academical. The great majority of them have had their day, but in London there still subsists the Royal Institution, and until very lately there did subsist the London Institution, as monuments of that movement in its most comprehensive character. Outside the metropolis, but with similar scope, the Royal Society of Edinburgh and the Philosophical Societies of Glasgow, Manchester, and Cambridge, survive from the same period, and more specialised societies, like the Linnæan, the Astronomical, and the Zoological are easily identified as being products of the same intellectual movement. These societies were formed to promote, not what may properly be called technical education, but rather the scientific education of the people, and, being self-supporting and self-contained, their membership was necessarily limited to the class of people who enjoy a certain affluence so as to be able to cultivate such tastes at an expenditure of leisure and money which, speaking generally, the artisan could not command. The older technical schools, such for example our own medical schools, or the St. Bride Foundation Printing School, and the various training schools for sailors and other particular crafts, were strictly professional and based upon the economical necessity of providing professional instruction. They did not depend at all upon the intellectual enthusiasm which generated these nineteenth century societies. These latter were essentially associations of amateurs, and consequently made their appeal almost exclusively to what we may call the leisured classes.

The temper of the times, however, deeply influenced as it was by the sentiment of the French Revolution, did not tolerate the limitation of educational advantages to well-to-do people. Political sentiment, and doubtless also a keen perception that intellectual tools, as well as material implements, should be in the hands of those who can use them, led to the growth of a movement, which soon became widely extended, for the special scientific training of workmen and artisans. This movement, when fully developed, became known by the specific name of Mechanics' Institutes. The first mechanics' institute was formed in Glasgow, and still exists in a highly developed form as the Glasgow Mechanics' Institute. The foundation of that institution was due to Dr. George Birkbeck. Started by him in the year 1800 A.D., at a time when he was a professor of the Glasgow University, and being then in the nature of what we should now call university extension, it was already well enough established to be self-supporting when, four years later, Dr. Birkbeck came to settle in London as a practising physician. The success of his Glasgow undertaking led to the formation of a similar institution in London. This in time grew to be the largest of all the mechanics' institutes, and still thrives under the transparent alias of the Birkbeck College. The success of these two undertakings led to the formation of similar institutions up and down the country, and so in these voluntary mechanics' institutes the great scheme of technical education took its modest rise.

The Mechanics' Institutes movement did not, however, completely satisfy the requirements of the case. The development of the factory system of manufactures had rendered the old apprenticeship method of technical education obsolete, and the voluntary association of workmen in mechanics' institutes was not sufficient to fill the gap. What was wanted was an agency which should act upon the young recruit to the ranks of the workmen and supply him with the instruction which, under a more domestic industrial system, he would have received from his master. The discovery of this need was no novelty. So early as the year 1754 the Society for the Encouragement of Arts, Manufactures, and Commerce in Great Britain had been founded with the object, among other things and very principally, of promoting a scheme for giving instruction in drawing to children and young people of the industrial classes. The work of that Society had been continuously carried on in this and certain other directions, but for

the first fifty years of its existence its operations had been upon too small a scale to have any marked effect upon the arts, manufactures, and commerce of the realm. With the quickening of the intellectual life of the British people in the early years of the nineteenth century its activities increased very notably, both in volume and importance. The mechanics' institute scheme, although independently developed, received efficient support from that Society and, what was of even greater importance from the present point of view, the Society succeeded in establishing a system of industrial exhibitions which, growing up from small beginnings, culminated in the International Exhibition of 1851. That congress, which, for the first time, brought together for exhibition side by side the products of manufacture from every quarter of the globe, served to reveal many things to the British people and their foreign guests. Chief among the lessons so brought home was the economic value of workmen's technical schools, so that the eyes of the industrial world were opened to the great truth which the founders of the Society of Arts had somewhat prematurely, and perhaps imperfectly, perceived. So marked was the impression produced by the International Exhibition of 1851 that the American "Cyclopædia of Education," in discussing the rise of modern technical education, traces it to four principal events, the first of which is the London Exhibition of 1851. From it our own Science and Art Department took its rise in 1853. The artistic rather than the scientific side of the undertaking at first engaged attention, but later on the Livery Companies of London, awakening to long-forgotten responsibilities, took part in the new movement and established the City and Guilds' Institute, which has become the parent not only of the great science school at South Kensington, but of affiliated technical schools in all parts of the realm.

The example thus set in Great Britain was speedily followed in America, and the second of the great events to which the American "Cyclopædia" attributes the rise of modern technical education was the passing of the Morrell Act in 1862, which provided for the setting-up of technical schools in the various States of the American Union. How comparatively late a comer Germany is in this field may be seen by the circumstance that the same authority cites, as the third of these turning-points in the history of technical education, the Franco-Prussian War of 1871.

Two circumstances have concurred to draw attention to the technical education system of Germany. The first of these is the enormous development of her industrial activity—a development which has in time coincided with the establishment of the education system, and which, to a certain large extent, has been traceably due to it. The other circumstance is that the German system of technical education is highly centralised in large and fully-equipped central schools. In this respect it differs very materially from the English system of technical education, which is based upon the idea of co-operation between the school and the factory. The apparatus of instruction, under the English system, is, therefore, largely out of sight, comprising, as it does, the appliances in actual use in workshops and factories. In Germany, on the other hand, the conductors of technical schools aim at superseding the factory altogether, and at giving practical as well as theoretical instruction in their laboratories. This difference of system is, perhaps, not always sufficiently regarded when comparisons are made between the British and German institutions of technical education. However that may be, the assessment of its value does not concern us this evening. Its only bearing upon the present discussion lies in the fact that, there being this highly efficient system in successful operation in a neighbouring land, it has naturally been the object of continuous study on the part of those among our own people who are particularly interested in the subject of technical education. Thus it came about that the German system was made the subject of an important report by the Society of Arts in 1867. Also it was made the subject of very thorough inquiry by the Royal Commission already referred to, which reported in 1884—well known as the Duke of Devonshire's Commission. It furnished material for a second report by the same Commission fourteen years later.

No doubt the great development of German industry in the course of the seventeen years which have elapsed since that last report to the Duke of Devonshire, makes it expedient that the subject should now be examined anew; but it is worth while to bear in mind that, from the first, the German system of technical education has been carefully studied by educational experts in this country, and the lessons which it teaches have from time to time been noted for the information of our own authorities.

Eminent—perhaps I might even say pre-eminent—among these experts is a very remarkable man who acted as Chairman of the

Devonshire Commission—the late Sir Bernhard Samuelson—to whose great public services in connection with the department of technical education Mr. Mundella, at that time Vice-President of the Committee of Council on Education, bore emphatic testimony in the House of Commons in 1881. The following is a passage from "Hansard," reporting what was said :—

"My honourable friend, the Member for Glasgow, said that at present we have no evidence before the House of what is being done in this matter [*i.e.*, the matter of technical education]—that we have up to a certain date, 1868 – but that since that time there has been a complete revolution ; and that 1868 must be regarded as an antediluvian period, as compared with the present day. But to whom were we indebted for the information supplied in 1868, and which, at the time, was very good information as to what had been done ? We have in the volumes which have been laid on this Table as good a statement of the condition of technical education in Europe in 1868 as it is possible to obtain, and we owe it, in a great extent, to the ability, intelligence, and public spirit of my honourable friend, the Member for Banbury [Mr. B. Samuelson], who forced it upon the attention of the House and conducted an inquiry in a semi-official capacity, at his own expense, the result being that he was able to produce a report that did a great amount of good and that led to very satisfactory results. I am very glad to find that the City Guilds are now following up his example."

I cite this testimonial to Sir Bernhard Samuelson in order that it may be abundantly clear that he cannot be supposed to be in the least disposed to undervalue the importance of technical education and its bearing upon the success of our industrial undertakings. In the year 1867 all the world was looking admiringly upon the high development and great prosperity of British industry. Just as we to-day speak with respect of the technical educational institutions of America, France, Switzerland, and Germany, so in 1867 those other countries were speaking with the like respect of our widely diffused mechanics' institutes and art schools. Sir Bernhard Samuelson, who was in personal contact with our industrial neighbours while at the same time he was an enterprising industrial captain himself in this country, was by no means satisfied that these developments, which attracted the favourable notice of our neighbours, were sufficient to do justice to ourselves. At great personal trouble and expense he produced the report of which Mr. Mundella spoke in such high praise, as a State document. Subsequently, in 1882, he became the Chairman of the Royal Commission known as the Duke of Devonshire's Commission. Some fifteen years afterwards, in 1897, the same Commission, with Sir Bernhard Samuelson still at its head, produced a second report, in which the further development of the technical education and institutions of Germany was made the subject of comparison with the past and with our then existing system. By this time (1897) the interest of the British public in the subject had been thoroughly awakened, largely by the labours of Sir Bernhard Samuelson and his coadjutors, but still more by the great development of German industry, in particular along certain lines—notably, electrical machinery and chemical products, upon which technical education had a very direct and important bearing. The appearance, therefore, of the second report of the Commission to the Duke of Devonshire gave rise to an important newspaper discussion upon the whole subject of technical education and its bearing upon our industrial success. This newspaper discussion furnished the occasion for a very remarkable utterance by Sir Bernhard Samuelson, an utterance which supplies the text upon which I desire to offer a few observations this evening. It is contained in a short letter to the *Times*, which appeared in the issue of January 25th, 1897, and runs as follows :—

"In your leader on the report of my late colleagues on technical progress in Germany, you refer to the fact that the production of dyes from coal tar, in which we have been so completely distanced by the Germans, was originated by Dr. Perkin, and, it might be added, by Dr. Hofmann in this country.

"It is not generally known that we lost this manufacture because the trade in England was shut up for fourteen years by a master patent whilst no controlling patent had been sanctioned in Germany, so that anyone could take up the manufacture there ; the result being, of course, development abroad in place of stagnation at home.

"At the present time we in this country are handicapped as much as before, but from an opposition (*sic*) of things. The Germans, having taken the lead with their acquired experience and large capital, keep it by patenting their new processes in this country, but carry out their manufacture abroad. So long as they keep our market supplied, which they take care to do, nobody is at liberty to make the patented articles here."

The fact that such a man at such a time should bestir himself to direct public attention thus pointedly upon the operation of the Patent

Law is a highly significant circumstance. Its full significance can only be appreciated by considering the facts of the case to which allusion is here made. That case was an action tried in our own courts in the year 1883, and brought by the Badische Chemical Factory against Levinstein and Company, a firm of dye manufacturers in Manchester. Seldom has an action of greater practical importance been the subject of proceedings in a court of law. Some indication of the importance of this decision in an industrial sense is given by the fact that it was referred to by Sir Bernhard Samuelson in the way that I have mentioned, but for a just understanding of its importance it is necessary to examine the report of the proceedings and the practical consequences in which they eventuated.

The German patentees in that case were the inventors of a dyestuff, a chemical body having a definite chemical composition and a specific name. It may be sufficiently identified for the purposes of this evening's discussion by speaking of it as a sulpho-acid of a coal-tar product yielding red and brown dyes. The substance has an ill-sounding chemical name which, however, is of no great importance in this connection, because the chemical composition does not suffice to determine the tinctorial value of the product. That depends either upon chemical properties too subtle to be defined by even the most outlandish name or upon physical properties, the nature of which was, and probably still is, unknown. In respect of the dyestuffs which they were the first to produce, the German patentees obtained a British patent which was unquestionably good. Those dyestuffs, however, were of no appreciable commercial value, for the simple reason that the dyes produced, according to the inventor's method of manufacture, did not succeed in catching the public taste.

The patent was taken out in the year 1878, and it was five years later that the action against Levinstein came to trial. The patentees then complained that a very successful red dye which Levinstein manufactured was an infringement of their patent. In the view which the court took of the nature of the patent this claim was upheld and judgment accordingly was given in their favour. But the circumstances were very singular, and such as to place the court in a difficult position when deciding upon the issue of fact. It was proved that the dye which Levinstein manufactured could not be produced by the processes which the inventors had described, indeed could not be produced by any process which was known to the inventors. The successful dye, which was taken to answer to the chemical composition of the patented invention, was produced by a secret process, and special arrangements were made for taking the evidence in such a manner that the Levinstein secret was not disclosed except confidentially to the court and its officers. The patentee, therefore, although he was allowed to restrain the second inventor from working his own invention in this country, did not acquire a knowledge of the nature of that invention. Thus the action resulted in a deadlock, and the operation of the Patent Law in this case was to banish the manufacture of the patented dye from this country altogether. The patentee could not make it because he did not know how, the real inventor could not make it because he was restrained by an injunction of the court. So it happened that by this perverse operation of the Patent Law a patent, which had been granted with the avowed object of introducing into this country the manufacture of the sulpho-acid dyestuffs, operated to prevent their introduction. In the end the manufacture was carried on in Holland, where the German patentees had been unable to obtain a patent. It must, of course, have been communicated to the Dutch manufacturers by the inventor, and it may be presumed that he was able, thanks to the absence of patent protection in Holland, to get, in the form of a secret process, the benefit of his own invention. But, however the inventor may have profited by that arrangement, the industry in this country suffered very heavily. I am not aware that any statistics have been published from which the value of the dye industry which was thus transferred to Holland can be ascertained, but I have been credibly informed that the cloth sent from Manchester to Holland to be dyed with Blackley red represented an industry which, in the aggregate, was worth many millions of pounds. This is the instance to which Sir Bernhard Samuelson refers in his letter to the *Times*, and it merits study at the present time because what happened in 1883 might equally well happen to-day under our existing Patent Law, and Sir Bernhard Samuelson's warning is of special importance at a moment when the investment of a large sum of money is in contemplation with the object of establishing an industry similar to that which was so ruthlessly destroyed by legal process in 1883.

To appreciate the bearing of this case upon the circumstances of the hour it is desirable to

look at the facts a little more closely. I have already indicated in broad outline what was the position of the manufacturer who was held to be an infringer. It will have been fairly obvious from that outline that he was not the unresourceful and unintelligent manufacturer at whose door the failure of the chemical industries is laid to-day. But this does not rest in inference merely. Let me read to you a short passage from the judgment, in which the learned judge refers to Mr. Levinstein's part in the transaction. The Levinstein process, as I have already said, was a secret process. It could not have been learned from the patentees or from their specification because they themselves did not know how to produce the dyestuff about which they complained. Levinstein, therefore, must have brought to bear upon the problem precisely those resources which it is the object of technical education to place at the manufacturer's disposal. So much may be inferred. Now hear what the judge says, speaking with knowledge of all the facts:—

"Then the result at which I arrive is this:—The processes employed by Mr. Levinstein are processes deserving of great praise; but they are simply processes which produce exactly the same results from the same materials which are produced by this patent. The same object is pursued, the same materials are employed, the same result is obtained. I cannot do otherwise than come to the conclusion that those are merely processes, that they are not a new invention differing from the patent, but are in reality the manufacture of sulpho-acids of oxyazonaphthylamine by a process differing in some respects from the process employed according to this patent.

"I cannot come to this conclusion, I must honestly say, without some regret. I think Mr. Levinstein has employed great knowledge, great skill, and great perseverance in finding out these processes, but I am sorry to say that the law compels me to inform him that these processes cannot be used in the production of this colouring matter, seeing that the production of this colouring matter is protected by a patent."

Now, in a case like this, it is quite impossible to attribute the loss of the industry to any defect in our system of technical education. The great skill, great knowledge, great perseverance which Levinstein had brought to bear were all to go for nothing because of the impracticable working of the Patent Law. For this reason it was that, when the newspaper press had got thoroughly excited upon the subject of technical education and the British inferiority to the Germans in chemical industry, a protagonist among the advocates of technical education warned them that not only technical education but the Patent Law also must be attended to if they wished to make their industry secure. This was written in 1897, but fourteen years before, that is to say in the year 1883, a Patent Act had been passed by which provision was made, among other things, for the remedying of the mischief which this case illustrates. It is not, however, to be supposed that the draftsmen of that statute had the facts of the Levinstein case in mind. That, indeed, was impossible. The Act was passed in 1883, and the action was only tried in that year. The consequences of the decision in that action could not possibly have been known until a later date. But although it had not been illustrated on so large a scale, the mischief was perfectly well known to students of our industrial development in 1883. It is not surprising, therefore, to find that an attempt was made to remedy the mischief. Before passing to the consideration of that, and other legislative measures which have been passed into law since the date of the Samuelson letter, it will be useful to get a definite idea of the essential nature of the mischief which calls for remedy.

It has been shown that the operation of the Patent Law in the Levinstein case was to render the use in this country of a valuable invention impossible, and to banish the resulting industry to Holland. It needs no argument to show that that is a complete miscarriage. The object of the Patent Law is to facilitate the introduction of new manufactures within the realm. Whether we look upon the patent as an instrument of public policy, or as a reward granted to a meritorious inventor, the result from this point of view is the same. The merit of the inventor or the object of the policy, as the case may be, is to secure the advantage of an improvement in manufacture for the benefit of the people of this realm. In law, no less than in policy, the outcome of the Levinstein case was absurd and lamentable. How, then, could such a result come about? The answer to that question is that it came about by the operation of the rule which makes an injunction by the court the remedy for an infringement of patent right.

Patent right in its beginnings was a right which enabled the grantee of a patent to carry on some craft within the realm, in spite of the privileges of chartered craftsmen. Prior to the year 1832 a large number of corporations

existed in various parts of the country for the purpose of supervising the industries and commerce of our cities. The great companies of the City of London are survivals from a very ancient period, and to this very day the authority of the Stationers' Company to keep the copyright register is a survival—rescued by special legislation from the repeal of 1832—of the ancient privileges of the Company in respect of the printing trade. In the seventeenth century these corporations of craftsmen, guilds, and companies, as they were variously called, were established in almost every township throughout the realm. Each guild enjoyed certain monopoly rights in respect of the craft to which it belonged and within the town in which it was established. Whoever desired, for instance, to set up as a draper in Cambridge must be free of the guild of drapers in that town. Otherwise he was not allowed to embark in trade as a draper there, any more than a newcomer at the present time is allowed to set up in the business of the more strictly organised professions without first obtaining a professional qualification. In many cases the trade qualification which is now under consideration could only be acquired by the method of apprenticeship, and therefore if a candidate for craftsmanship was unable to pass through the stage of an apprenticehood he might do one of two things. That is to say, either he must abandon his candidature, or, as an alternative, he must obtain a grant from the Crown which would override the privileges of the guild. There is a very interesting illustration of this point in the "Remembrancia of the City of London" (p. 101), where appears a complaint by the Stationers' Company of a patent granted to one Woodde for printing on parchment, the complaint being that the patent enabled the patentee to set at nought the Company's charter and to encroach upon its privileges. Now in those days a patentee, who wanted to introduce a new manufacture, would find himself blocked on every side by such guild privileges. If he wanted to sell ironware in London he must get himself made free of the Ironmongers' Company, or, failing that, he must employ some member of the Company to act as his agent for the purpose of his business, or, as a third alternative, he must get a patent from the Crown which would enable him to carry on his trade in spite of the Company's exclusive privileges. It is, I think, made clear by the circumstances and language of the earliest patent grants that this was the principal motive with which inventors and projectors applied for grants of that kind. Unless he chanced to be a member of the craft with which his invention was connected he could not, without such a special grant of privilege, himself carry on the business which he proposed to set up. Even if he were a member of the necessary guild in London, that would not enable him to practise his craft in Norwich, say, or in other provincial towns where a privileged guild existed. Hence, for the establishment of a new industry which might be expected to develop in various parts of the kingdom, a special Royal grant would in any case be indispensable. Greatly as our circumstances have changed at the present date, a patent grant, as it is issued from the British Patent Office at this very time, contains the words which are appropriate to such a case. The King still grants his "especial licence, full power, sole privilege and authority that the said patentee by himself, his agents or licencees, and no others, may at all times hereafter during the term of years herein mentioned make, use, exercise, and vend the said invention within our United Kingdom of Great Britain and Ireland."

These words have seemed unintelligible to some modern lawyers, who, in the free trading conditions of the present day can discover no advantage in the Royal licence and authority, and, indeed, if the grant had contained nothing more than this it would by this time have grown obsolete, for the last legal obstacle to the establishment of a new manufacture within the realm was swept away by the Act which abolished the old corporations in the year 1832.

The patent grant, however, always contained, in addition to this enabling clause, a further clause which is in the nature of an inhibition, and which strictly commands "all our subjects whatsoever . . . that they do not at any time during the continuance of the said term of fourteen years either directly or indirectly make use of or put in practice the said invention . . . without the consent, license, or agreement of the said patentee." This inhibition was, no doubt, from the first a very valuable part of the patent grant. In later years it came to be the whole substance of the grant. Two ways of giving effect to it are known to our law. One is the old common law remedy of damages obtainable by the patentee in an action against the infringer for an invasion of the chartered monopoly. The other is the remedy, originally only obtainable in Equity Courts, of an injunction to restrain continuance of the infringement.

Of these two remedies patentees have from very ancient times, as a rule, preferred the latter, and for what, from their point of view, are very good reasons. An injunction is a legal device for stamping with the character of crime an act which intrinsically is merely breach of contract or some private wrong. An ordinary breach of contract, such for instance as a failure to deliver goods sold at the time agreed upon for delivery, gives rise to an action for damages, and the measure of relief which the court can give to the aggrieved plaintiff is the damage which he has suffered by reason of the breach. There is here a very nice adjustment of the remedy to the mischief. The parties are put, as nearly as it is possible to put them, into the position which they would have occupied if the contract, instead of being broken, had been properly carried out, and that, speaking generally, is the mild and reasonable result which the rule and procedure of the common law is designed to bring about. There is nothing vindictive or exemplary about it. Indemnity to the plaintiff who has suffered the wrong is all that the system is intended to secure.

The alternative remedy, by way of an injunction, is almost the exact reverse of this. It is based upon the rigid rule, *fiat justitia, ruat cœlum.* The court interposes its authority between the disputants, ascertains what is the right thing to be done, and then requires the defeated defendant to do that thing, not as an act of duty to his neighbour, but as an act of obedience to the court. Failure to obey is visited with the penalties, not of breach of duty, but of crime, and that crime one of the highest known to the law —namely, contempt of court, the penalty of which is imprisonment at the discretion of the judge. The substantial injury to the plaintiff has no bearing on the measure of the relief afforded under this ferocious system. When once an injunction has been issued the court is disabled from thereafter doing justice between the parties. When next the question arises, it will arise not as a complaint of private wrong, but as a charge of criminal contempt, and will have to be dealt with accordingly, without, in strict theory, any regard to the merits of the underlying controversy between the parties to the cause.

It is not surprising that with a weapon of this kind ready to hand patentees have always been more anxious to obtain an injunction than to secure an award of damages. In the times of James I., when our Patent Law first took its statutory form, the principal Court of Equity, under Parliament, within the realm, was the Privy Council which, sitting in two committees under the names of the Council Board and Star Chamber severally, exercised an equitable jurisdiction. To this tribunal the patentees had recourse, and from it they were accustomed to obtain, with fatal facility, injunctions in support of their patent rights. So oppressive did this procedure become at that time that the original Statute of Monopolies, by a provision which still stands upon the statute book and is entitled in courts of law to such consideration as is accorded to ancient statutes, declares "that all proclamations, inhibitions, restraints, tending to the instituting, erecting, strengthening, furthering, or countenancing of any grant of the selling, making, working, or using of anything within this realm is utterly void and of none effect, and in no wise to put in execution." In furtherance of this sweeping abolition of the power of the courts to grant injunctions in support of patent right, it was further provided that the force and validity of all such charters, patents, restraints, or the like, should be for ever thereafter examined, tried, and determined by and according to the common law of this realm and not otherwise. The Statute of Monopolies, like other statutable provisions for the protection of the public against the encroachments of patentees, has had an unfortunate history. Treated with contempt by the servile courts of the Stuart times, it has been simply forgotten and ignored in later times, and has never had its designed effect. In spite of its stringent provisions, the injunction is to-day what it was in the days of Elizabeth and James I., the main support of patent right, and, as the case quoted shows, it has been used in modern times with effects even more disastrous for the industry of this country than in those ancient days, when it aroused the hostility of Lord Coke and the antagonism of a reforming Parliament.

Such, stated in general terms, is the nature of the mischief to which Sir Bernhard Samuelson drew attention. To appreciate the magnitude of its effects it is necessary to recur to the narrative of events. Enough has been already said about the mischievous effect of this particular injunction upon the dyeing trade of Lancashire. In fact, however, the whole subject of chemical industry is involved, and therefore the facts with which we have to deal cover a very much larger field than this particular sulpho-acid dye, a field in fact much larger than

the field of dyestuffs, a field which is larger even than the whole chemical industry. We may, however, be content this evening to deal with that aspect of it with which we are more immediately concerned—with its bearing, that is to say, upon the proposal to establish dye manufacture upon a very extensive scale within this country.

From that point of view the important fact in the Levinstein case is, not that the manufacture of a particular dye was prohibited within the realm, but that the way of improvement was closed. The peculiar mischief of this decision was that it made it more advantageous for an inventor who improved upon the original patent to go to Holland and practise his improved invention as a secret process than to practise it in this country under the provisions of our Patent Law. To establish such a state of things was obviously cutting at the root of development. What is the use of introducing improvements and developing new inventions if the inventor is to be told that this is only an improvement, and therefore cannot be practised within this realm? A few carefully disposed patents can, under such a system, block the whole development of an industry against all the world except only those privileged people who chance to be the holders of the pioneer patents. It is a matter of no consideration that these pioneer patents themselves may be perfectly worthless for all practical purposes. It is their existence, not their merit, which constitutes the strength of the patentee's position.

This situation was clearly apprehended at a very early date in the history of the chemical industry by our German competitors. A system of blocking patents has been an organised industry with the great German manufacturing chemists at least since the year 1883, and when we hear of the large staffs which they keep employed upon research work in their factories, it is well to remember that, over and above those results of this laboratory industry which take effect in improved processes and products, there is a large output of novelties which are improvements only in a legal sense; the real value of which is that they eventuate in patents of this blocking type which close the avenues of improvement to other inventors.

It is impossible from any available data to ascertain to what extent the British chemical industry has been sapped by means of such mischievous patents, but I imagine that no one having a practical acquaintance with that industry will have any doubt that this system of sapping has been systematically and extensively developed, and that it has had an immense success. It is well that the industry and resourcefulness of the German manufacturers and of their laboratory staff should be recognised. It may be freely admitted that our own people may learn much from their German competitors in this respect; but when we are comparing the relative positions of German and British chemical manufacturers in the markets of our own country it is mere obscurantism to leave out of account this crafty and successful exploitation of our Patent Law to the detriment of our own industry.

In all these cases the cause of our weakness is the injunction. It is to be understood that, according to the practice which prevails to-day, a perpetual injunction is granted as a matter of course to protect a patentee who has successfully established his patent rights against an infringer. A perusal of the text-books might easily mislead a student of English law, for dicta are to be found to the effect that an injunction is a remedy the use of which is in the discretion of the court, and which will only be applied for good reason, that when the common law remedy is sufficient the plaintiff should be left to that remedy and no injunction should issue. If this principle were observed in practice it would secure the public against the great mischief which has been just described, but in fact these sound principles do not apply in the administration of the Patent Law. Judges have long since ceased to exercise any personal discretion in the exercise of the jurisdiction to grant injunctions in ordinary patent actions. The relief is asked for as a matter of form in the pleadings, and is added as a matter of course to the judgment, so that an injunction to restrain the use of the patented invention in any form and in any measure has come to be regarded as the legal right of a successful patentee.

Such being the mischief, we may now turn to consider what are the remedies which Parliament has provided. Leaving out of account the Statute of Monopolies which, though unrepealed, has become, as above stated, obsolete and ineffective, we find the earliest attempt embodied in a section (22) of the Patent Act of 1883. That enactment provided a remedy which has come in recent years to be well known under the style of a compulsory licence. By virtue of the provisions of the section any person interested might apply to the Board of Trade for a compulsory licence, alleging one or other of the following grounds:—

(*a*) That the patent was not being worked in the United Kingdom; or

(b) That the reasonable requirements of the public with respect to the invention could not be supplied; or

(c) That any person was prevented from working or from using to the best advantage an invention of which he was possessed.

The Board was empowered to deal with the petition and in a proper case to order the patentee to grant licences on such terms as to amount of royalties, security for payment, or otherwise, as the Board, having regard to the nature of the invention and the circumstances of the case, might deem just.

If this contrivance of a compulsory licence had been effective, it would have met the whole difficulty. It would have prevented the mischiefs which have arisen, and if an expression of opinion may be allowed in this connection, it would, I think, have placed the Patent Law of this realm in an entirely sound position and constituted it a worthy model of Patent Law throughout the world. But a very hard fate has pursued the reformers of our Patent Law. This provision, like the corresponding provisions of the Statute of Monopolies, was still-born and never produced its intended result. In the case of the Statute of Monopolies, which was admirably drafted, the mishap arose from the opposition of the Court, and the exercise under our Stuart monarchs of a royal authority which dispensed with statutes. In the case of the Patent Act of 1883 the result was due to faults of draftsmanship and these faults were three.

(1) The operation of the clause was suspended for an indefinite period of time, but a period so long that before it elapsed the statutable remedy had been itself forgotten.

(2) The machinery provided for administering the Act was novel and ineffective.

(3) The procedure prescribed involved a multiplication of proceedings and consequently inordinate expense.

It will be well to bestow a little attention upon each of these points, for they have a very close bearing upon the efficiency of all sorts of legislative reforms.

Taking the first point, it must be explained that the Act of 1883 contained in its forty-fifth Section a provision in the following terms:—

"Every patent granted before the commencement of this Act or on an application then pending shall remain unaffected by the provisions of this Act relating to . . . compulsory licences."

The idea, no doubt, was that the liability to grant compulsory licences was a burden with which it would not be fair to load the already vested rights of subsisting patentees. That view of the matter opens the door to a very interesting discussion, which, however, it would be unprofitable to pursue in the present connection. Suffice it to note the apparent reason for what turned out to be a very unfortunate exception. At the time when the Act passed, and for some years afterwards, the only patents in respect of which anybody could be interested in asking for a compulsory licence were covered by this exception, so that the intended relief took no immediate effect. An old adage reminds us that what is out of sight is out of mind, and it may be generalised into a dictum that what is out of use is very soon forgotten. So it happened that this provision with regard to compulsory licences was professionally forgotten. Not for a period of fourteen years after the date of the Act did anybody attempt to take advantage of the relief which the Act provided. In 1897 a book was published which drew the attention of lawyers to this forgotten enactment, and, following upon the publication of that book, came a series of applications to the Board of Trade for the grant of compulsory licences. By that time, however, the mischief had become very serious, and it was difficult to persuade a public, which was now thoroughly alarmed, that a remedy, which for fourteen years had done no good, could really be fraught with any remedial virtue. Hence the first attempts to utilise these provisions coincided with a serious agitation for relief in some more effective form, and under such conditions only an exceedingly available and serviceable contrivance could be made to succeed.

This brings us to the second criticism above indicated. A blind prejudice against the High Court of Justice has repeatedly in recent years led to the delegation of judicial duties to officers who are not judges. I speak of this prejudice as blind, not from any notion that the High Court is a faultless tribunal, but because it has frequently happened, as in this case, that the tribunal selected to replace the High Court is faultier still. From what has been said above concerning the mischief against which a remedy had to be provided, it will be evident that the compulsory licence was, or ought to be, intended to be an alternative to the injunction. Nothing could have been more unseemly, if it had occurred, than the issue by the Board of Trade of compulsory licences to defeat the mischief produced by perpetual injunctions. The ground usually taken by persons who advocate the

setting up of special tribunals for the administration of statutable relief is that proceedings in the High Court are expensive and dilatory. Now, whatever may be said for such a contention in some other cases, there was nothing whatever to be said for it in this. The proper time and place for the discussion of an alternative remedy is when and where the principal remedy itself is under discussion, and nothing could well be more perplexing than the procedure of this Act, which left the High Court the victim of a vicious rule concerning the granting of injunctions, and vested the remedial authority in the Board of Trade, where independent procedure involved additional expense and collateral jurisdiction gave rise to the risk of conflicting authorities. In fact, the result of this inconvenient arrangement was that inventors, the people who suffered from the injunction, took no benefit from the licence, and inventors who applied for the licence had to grope their way through the difficulties of an undeveloped and imperfectly settled procedure.

Incidentally, it has just been mentioned that the machinery prescribed by the Act involved a multiplicity of proceedings. The incidental expense arose not simply from the circumstance that proceedings were multiplied, but in a still larger measure from the circumstance that the tribunal itself was unknown. The course adopted by the Board of Trade when petitions under this Act came before it was, after preliminary discussion more or less in the nature of pleadings, to appoint an arbitrator to settle the terms of the proposed licence. The arbitrator was appointed *ad hoc*, and did not in any sense constitute a court. What view he would take of even the most fundamental questions was unknown, and in a case of any consequence, therefore, it was thought necessary to bring to bear upon him the heaviest artillery of advocacy that was available. It turned out, in the event, that proceedings before the Board of Trade were in fact quite as expensive as an action at law. If the proceedings had been a mere incident—the trial of a separate issue in an action at law—they would have added something, but something not very material, to the expense of the action. But, seeing that they had to be carried on independently of the action, there was a considerable risk of their doubling the expense. Even when the foresight of an applicant for a compulsory licence led him to take the bull by the horns and, without waiting for the patentee to bring an action, to launch his own petition, he saved no costs because, as has been already said, the proceedings at the Board of Trade were no less expensive than proceedings in the High Court.

It will now be easily understood that under these conditions the provisions of the Act of 1883 concerning compulsory licences were never tested experimentally, for, although several petitions were lodged and carried through to a conclusion, they were all carried through under such unfavourable conditions that anything more than an unsatisfactory success was rendered impossible. It is not surprising, therefore, that the agitation already referred to for a reform of the Act of 1883 should have gathered head and eventually should have prevailed in Parliament. In 1900 a Departmental Committee was appointed to consider further remedial legislation, and in particular to advise Parliament as to the adoption of the Continental provision of the compulsory working within the realm of patented inventions. The Committee reported against the compulsory working provision, and in favour of a reference of petitions for compulsory licences to the High Court. The report contained also some other suggestions, and in the ensuing year Parliament proceeded to legislate generally on lines indicated by the Committee. Instead, however, of adopting the suggestion that petitions for compulsory licences should go to the High Court, Parliament took the extraordinary course of sending them for consideration to the Privy Council. This expedient did not help matters at all. The division of authority was still as marked and as mischievous as when the petition was sent to a referee, and the practice of the Privy Council tended rather to aggravate than to reduce the costs incidental to the carrying of the petition through. So far the last case was distinctly worse than the first, and in 1907 Parliament proceeded to deal with the matter for a third time.

The Act of 1907 was closely modelled upon the German patent law. Accordingly a new remedy was introduced in the shape of a condition making the working of a patented invention within the realm compulsory. The Act of 1907, like much more of the recent work of Parliament, is rather in the nature of a legislative project than of a piece of accomplished legislation. The principle of compulsory working was enunciated, but the nature and measure of the working to be required and the conditions which furnished an excuse or imposed liability upon a patentee were left to be settled by the judges in the administration of the law.

It was probably a wise expedient on the part of Parliament to leave these matters thus in a plastic condition to be moulded and fixed by the action of the judicature. The idea no doubt was that the obligation of compulsory working would, on the one hand, discourage the practice of taking patents for the purpose of blocking an industry, and, on the other hand, would secure the development within the realm of industries which are protected by patent right. The Act has only been in operation for a period of about seven years, and it is too soon perhaps to attempt anything like an estimate upon historical foundations of its possible outcome. It may be pointed out, however, that it has not had very much effect so far upon the chemical industry. To those who have a practical acquaintance with the conditions of the problem this will not be surprising. The complications which it presents in its judicial aspects are enormous. In part they may be illustrated by the facts of the Levinstein case which have been described. In such a case as that, for instance, where there was no market for the goods which the patentee could manufacture and a large market for the infringing goods which he did not know how to make, what is the patentee's obligation under the law of compulsory working? Must he manufacture, to satisfy the law, a certain quantity of unmerchantable goods, or is he to be held liable to manufacture the improved goods whose production is the infringer's secret? A court which will say to him, you must secure the Blackley red manufacture under the penalty of losing your patent, but which at the same time granted an injunction based upon the patent to prevent the only man from manufacturing Blackley red who had the necessary knowledge —such a court would obviously be placed in a position of great embarrassment. Questions of that sort, which simply do not admit of a satisfactory solution, arise in a variety of ways out of this ill-digested scheme of compulsory working. The inherent difficulties are such that nothing would be less surprising than that it should be found in the end to be what it appears to have been in the beginning, an expedient wholly ineffective for any useful purpose.

By the Act of 1907 the Legislature at last took the obvious course of sending a petition for compulsory licence to be dealt with by the Court. Yet even here the perplexity of double proceedings was carefully preserved. The High Court was substituted for the Privy Council, not for the Board of Trade, and consequently the root of the mischief remains. It is still not possible by simple proceedings in the nature of counterclaim to bring the issue of compulsory licence before the same tribunal which tries the action. A defendant who wishes to get the benefit of the statutory relief must reply to the attack upon him not only by putting in a defence in the High Court, but also by instituting proceedings by way of petition to the Board of Trade. The proceedings must go on together but independently the one of the other, and it is conceivable that by management things might be so arranged that ultimately the petition and the action should be heard together. This, however, has never yet occurred in practice, and consequently, even under the Act of 1907, the compulsory licence provisions have had no effect upon the difficulties which arise out of the perpetual injunction.

Such being the situation which has actually arisen, it will be useful to consider the bearing of this situation upon the proposal now made to establish, in competition with the German industry, a self-sufficient industry in this country in the manufacture of dyestuffs. We may take it for granted on this occasion that no insuperable difficulty will arise. So far as research and technical education are concerned, there is not likely to be the smallest difficulty about securing, and at once securing, the necessary trained skill. Whether our own technical schools have produced a sufficient number of qualified men I do not know, but in discussing this question it must be borne in mind, that, so far as the technical chemist is concerned, technical schools are, for all practical purposes, international institutions. The young men trained in the schools of Germany and Switzerland are, and always have been, as obtainable by our manufacturers as by manufacturers abroad in any numbers in which they may be wanted. It is not, if I understand aright, in this direction that the critics of our technical educational system find fault with it. The fault they find is first with the manufacturer, inasmuch as he does not take advantage of his opportunities in this direction of securing skilled assistance, and in the next place fault is found, I suppose, with the foremen and skilled artisans in that their knowledge is not so scientific as it should be, but partakes too much of the nature of perpetuated and unintelligent tradition. Now it is obvious that both these deficiencies can be made good at no great distance of time. The employment of research chemists and skilled directors in any numbers that may be

found desirable is the sort of thing that could be effected at once by an institution such as it is now proposed to set up. On that score, therefore, the difficulty is one that can be at once and easily surmounted. The training of the artisan is, no doubt, a thing less easy to accomplish in the sense that it demands more time for its accomplishment. But with the resources of such an institution it would be easy, by internal arrangements, to secure the necessary practical and theoretical instruction, and in the course of a few months to form the nucleus, at least, of such a staff as is desired. That again, therefore, is a difficulty which at any rate a short time would dispose of.

Let us assume that all these things are done, that the works are started and in successful operation. That fact will not make any difference to the subsisting patent rights in this country of which, as it is well known, a very large proportion are held by foreigners and others whose interest it is to favour the foreign competition with this domestic industry. Now it is clear, therefore, that there will be a strong disposition to repeat the Badische coup of 1883, and then, adopting the language already quoted from the judgment in that case, we may say that notwithstanding "the great knowledge, great skill, and great perseverance" which will be brought to bear in building up these industries, the law will be invoked to say that the processes so developed cannot be used in the production of the colouring matters manufactured because the production of those colouring matters is protected by patent rights. It may at once be admitted that the new institution will be placed in a very different position from that which was occupied by the defendant in the Badische and Levinstein action. In the present case there is a possibility of applying to the Board of Trade for a compulsory licence, and if it were certain that such a proceeding would succeed it would in substance remove the difficulty. There would still be an important question of procedure to be considered, but that is probably not of sufficient importance to warrant a digression upon that topic this evening. I therefore pass that by. It cannot, however, be taken for granted that an application for a compulsory licence would succeed. The grounds on which such an application can be made are strictly limited and, in fact, very narrow. If the patentee himself takes adequate steps to supply the British market with his patented goods, then, according to the interpretation adopted by the courts of this provision of the statute, no order for a compulsory licence can be made. Now, in the case at least of important goods for which a large and profitable market exists, there seems to be no conceivable reason why the foreign patentee himself should not supply the demand. It is quite true that he may be called upon to conduct his manufacture within the realm, but he cannot be called upon, as matters stand, to grant a licence to the new institution. He may prefer to remain an active and privileged competitor with the new institution, and so, although with diminished power of mischief, may still succeed in casting his blight upon the undertaking. The carrying on of the new industry under these conditions would seem likely to be extremely fruitful of litigation, but by no means equally assured of success, for if it were possible to close any particular manufacture down as the result of a successful patent action, then it cannot be denied that nobody at the present moment is in a position to say what precise field of industry will in the end remain open to the proposed institution. This is the difficulty with which, as it seems to me, the promoters are faced. The research work of the laboratories of which we have lately heard so much has resulted in an immense and extremely intricate network of patents designed to protect, by their entanglement, the whole field of chemical industry which the Germans have made their own. Hitherto these entrenched patents have afforded very efficient protection, partly, no doubt, because the defence of the British industry has been left to the uncoordinated efforts of British manufacturers who have been attacked one at a time and beaten in detail. It does not, of course, follow that it would be equally successful against a fully-organised effort to create a British industry, but, on the other hand, nobody can be justified in asserting, as our Patent Law is understood and administered at the present time, that such a large and organised institution would have any better chance than the resolute manufacturer, like the Levinstein Company in 1883, of making an effective stand against the overwhelming brute force of a judicial injunction.

It would not be worth your while to have listened to my complaints this evening if they resulted in a mere jeremiad. It is because I hope to draw your attention to a solution of the problem that I have trespassed so long upon your patience in the way of stating it. I do not propose to bring before you any nostrum of my own, or any new project. The problem is an old one, and one which, as I venture to think

can be adequately dealt with on the accepted and established principles of English law. With your permission, I will state those principles as succinctly as I can, and will indicate how it has come about that they should have been departed from in connection with the present administration of the law. My suggestion will be that you should consider whether it would not be a useful reform to recur to those well-established and approved principles, and by legislative action if necessary, by judicial proceeding preferably, to bring back the practice of the courts to the line from which it ought never to have deviated.

In the first place, it is important to realise what the essential nature of a patent right is. In legal phrase it is a privilege, that is to say, it is a right specially conferred upon some individual, or some class, and not common to the whole society. The term "privilege" has, perhaps, a somewhat odious sound, because privileged classes or persons are, and always have been, apt to strain the limits of their privileges, and by their means to pursue illegitimate ends. But a legitimate privilege is a right that is granted, not in the interests of the privileged person alone, but equally in the interests of the community at large. For example, we grant to doctors the privilege of administering poisons in the interests, not of the doctors themselves, but of their patients. We grant to members of Parliament the privilege of making defamatory statements in the House, because it is a public interest of extreme importance that discussion there should be wholly unfettered. We grant to any man who is attacked the privilege of defending himself by all necessary violence when gentle means of defence are not available. A man who is waylaid may defend himself by violence, which, if it were unprovoked, would expose him to a civil action, or to penalties of a criminal assault. Speaking generally, it may be said that privileges are conceded, under our institutions, for the purpose of enabling persons on whom some duty is cast to discharge that duty.

This is the general principle upon which privilege is based, and this general principle applies in its integrity to the privileges which the Patent Law confers. It is largely taken for granted in the drafting of a modern patent, because it has again and again found expression in judicial statements. But in the earlier patents, when the system of granting such privileges was new, it was thought desirable to instruct not only the patentee but also the judges in the motives of the grant, these motives were set out more fully in the grant itself. An extract from a patent grant in the year 1618 will make this clear:—

"And Whereas it is supposed that the said several Engines are the proper invention of the said John Gilbert and are likely to prove of good and necessary use for the Service and Benefit of this our Realme.

"Know ye therefore that Wee

"Tendring the common Good and Benifit that may redound hereby to our said Realme and Subjects and intending to reward and recompence the Industrie Travaile and Charges of the said John Gilbert bestowed and expended in and about the investigation and fynding out of the said Inventions Engines or Instruments above mentioned and the better to encourage other of our Subjects in such lawfull and commendable Labours and Indeavors as may tend to good Use and Service in this our Realme, without just cause of Greivance to anie our Subjects, at the humble Petition of the said John Gilbert, and in consideration of the yerelie Rent in and by these Presents reserved and payable to Us our Heires and Successors,

"Of our especial Grace, certain knowledge and meere Motion, have given and graunted, and, by these Presents, for Us, our Heires and Successors, doe give and graunte full and sole Licence, Power, Priviledge and Authoritie," etc.

Ori . ally, at that date, as I have already pointe l out, a grant of authority was necessary to enable the inventor to override the chartered privileges of the craftsmen guilds. But, in fact, it went beyond that point, and conferred upon the inventor of this new device the same rights of exclusive manufacture which the chartered craftsmen themselves enjoyed in their own localities and in respect of their several crafts. In other words, the patentee was placed in the position of being made free of all the guilds up and down the country in respect of the manufacture which he was proposing to introduce, and at the same time he received a privilege which was apparently exclusive of the guilds themselves—although based on the analogy of their own privileges, so far as his own invention was concerned. Such was the original scheme of an English patent grant, and it was out of that original scheme that the modern patent grant developed. Now it will be seen that the grant of a patent right of this nature could not, it may be added that in fact it did not, preclude the Crown from making a still further grant to some other patentee which would override the first grant exactly as this had overridden the charters of the craftsmen. It was by such

means of overriding grants that the difficulty of the injunction was overcome in the early seventeenth century. A very interesting instance of that procedure occurred in connection with a very famous patent granted for the manufacture of glass, a grant specifically referred to in the Statute of Monopolies. This glass patent, when originally granted, was subject to a heavy rent to the Crown, amounting in fact to £1,000 a year. It was also subject to rents that were heavier still to mortgagees who had advanced money to the patentee to enable him to set up works. The whole result was that the adventure came to grief. The undertaking was so over-capitalised by these charges improvidently made that it could not be worked to anybody's advantage. The patentee could make no profit, and the rent chargers could not draw their revenues. From these circumstances a deadlock arose, the nature of which is not precisely known. It may very reasonably be conjectured, however, that some of the rent chargers were not willing to forego their interests or to make such sacrifices as would enable the undertaking to be placed on a sound footing. Probably what happened then was what would almost certainly happen now in like circumstances, that is to say, every one of the encumbrancers would try to shift the burden upon other shoulders, and would be so resolute in pursuing his own relative advantage that a mutual understanding would become impossible. To get over this difficulty, for the patentee was a man with great interest at Court, the King issued a second patent in respect of the same project, which authorised the grantee, who was in fact the original patentee, the encumbrancers being left out, to carry on the manufacture on his own account. This second patent was to override the first in so far as it authorised the grantee to carry on the undertaking in spite of the exclusive rights conferred by the original grant. In fact, this second patent treated the first patent in exactly the same way that the first patent had treated the charters of the guilds. The Crown forewent its rent of £1,000 a year, and, so far as the records go, it would seem that the original encumbrancers were left entirely out in the cold. What arrangements may have been made with them privately we have no means of knowing. It is not necessary to assume that any spoliation or fraud was covered by this second grant. The point of interest is that when, during this formative period of our Patent Law, the difficulty arose of an industry which was hampered by a mischievous patent, the knot was promptly cut by the grant of a licence from the Crown exactly analogous to the compulsory licence of our own days.

It will be observed, however, that here the discretionary power to grant the compulsory licence was not hedged about by strict limitations such as those which have been introduced into our modern Acts of Parliament. There is no reason to suppose that this power of the Crown to grant a compulsory licence has ever lapsed, and it is probable that if the matter were judicially investigated it would be found that the Royal Prerogative is sufficient to meet any case that can arise. It must, however, be admitted that an idea prevails at the present day that, so far as the Crown is concerned, an earlier grant overrides a later. The suggestion therefore which a study of the Constitutional question brings to light has no direct practical bearing. Before investors could be advised to subscribe capital on the faith of such a view of the law, the view itself would have to be considered by the tribunals and authoritatively pronounced upon. It is worth while to draw attention to it, because when amendments of the law are under consideration it is always of importance to ascertain what the law actually is which it is proposed to amend; but beyond that the only value of this ancient precedent is that it suggests a definite alternative to our present system which is worthy of consideration. We are led to inquire, if this is the law of the Constitution, why should the statute law impose more restricted limitations upon the power of granting compulsory licences?

The discussion of that question brings us back at once to the consideration of the nature of patent right. Is it in the nature of things a privilege of such a character that it would be impaired for the purposes of beneficent operation by being subject to a larger discretion in the Crown in the exercise of its dispensing power than the Patent Act recognises? The objects of the grant, as set out in the authentic document just quoted, are threefold:—

1. The common good and benefit to the realm.

2. Reward and recompense for the industry, trouble, and charges of the patentee.

3. The encouragement of other inventors in such laudable and commendable labours as may tend to the good use and service of the realm.

Now it is obvious, and may be taken to be generally admitted, that such an absolutely

unrestricted power of exclusive manufacture as was conceded in the Badische and Levinstein case tends directly not to promote, but to subvert the first of these objects. It tends also to produce that just cause of grievance which it was one of the declared objects of the Crown to avoid in connection with the grant. Hence it may be said, with confidence, that the relief by injunction which was granted in that case is subversive of the objects of the patent grant itself. The practical question, therefore, is not whether the power to restrain infringement by injunction shall be wholly uncontrolled, but to what extent it should be controlled. The obvious answer to this question is that it ought to be controlled to such an extent as to secure all the objects of the grant; including the avoidance of any just cause of grievance. An answer in those terms, however, is not very instructive, because the practical difficulty is to discover those rules of practice which will attain the end. One inference may, however, with confidence be drawn even from this extremely indefinite statement of the principle, and it is this: The injunction ought not to go as mere matter of course, and without consideration of the circumstances of the case. A court, when granting an injunction, ought to satisfy itself that the injunction will not cause the inconveniences which followed in the Badische case, and, therefore, something more than mere infringement ought to be established to justify a court in granting a perpetual injunction.

This view is in fact traditional with the English common lawyers, and finds its most authoritative expression in the Statute of Monopolies. Reference has been already made to that famous statute, and the passage has been already quoted which enacted that no injunction shall issue in support of patent right. The proceeding against which that enactment was directed is precisely this of an injunction which went as a matter of course, and without any regard to the special merits of the particular case. The mischief with which the Parliament of that date, with Sir Edward Coke as its leader, in connection with the passing of this statute, was concerned was the procedure adopted in the Star Chamber. It would seem that that court had adopted the practice of treating all infringement as contempt because the King's prohibition in the patent grant addressed to all and sundry, and forbidding them to make use of the invention without authority from the patentee, was taken to be of the same force as an injunction by the court itself. This undoubtedly was a more logical view than that which has obtained in more modern times, for it is difficult to see why a breach of the Royal injunction contained in an order of court should be treated as something more criminal than a breach of the Royal injunction authenticated by the Great Seal. In practice, of course, there is a good answer to the merely logical point. The judicial injunction is treated as being a matter of greater consequence than the Royal injunction simply because the judicial injunction proceeds upon a preliminary investigation into the validity of the patentee's claim. The Royal injunction, on the other hand, is issued at the mere petition of the patentee and without any full investigation of his right to the claim that he makes. The civilians, however, who supplied the controlling influence in the Equity Courts of the earlier half of the seventeenth century, had not arrived at the stage of dealing with an exercise of the prerogative in this critical spirit. That was the attitude of the common lawyers only, and this fact explains the preference that the Stuart monarchs showed for the civilian as against the common lawyers of their day. To the mind of the civilian a proclamation, or an injunction, or any other document authenticated by the Great Seal, was a thing to be implicitly obeyed. If the Great Seal had been wrongly applied there was a Chancellor who had authority, proper proceedings being taken, to cancel it. But so long as it remained uncancelled no subject, in their view, could be heard to call it in question. Hence it was that the Statute of Monopolies, which abolished this jurisdiction in theory, so far as patent rights were concerned, was framed with such vehemence as you have observed in the extract which I just now read. The same intolerance was manifested by the free English of other claims made in behalf of the Crown to exercise arbitrary power, and resulted, a little later in our history, in the abolition of the Star Chamber Court itself. It may, perhaps, be argued that, with the abolition of that court and the final disposal of the claim of the Crown to legislate by arbitrary authority, these sections of the Statute of Monopolies became obsolete. That, however, is a question which may perhaps some day have to be argued in a court of law. At any rate, it is one upon which it would be very imprudent to embark on the present occasion.

But, whatever the statutory rights of the public may be, they are ineffectual at the present time to afford protection to the public

against the mischief of perpetual injunctions improvidently granted. There is yet another line of authority which warrants the claim of the public to judicial consideration in this matter, and those authorities are to be traced in the reports of our Chancery Courts. The struggle between civilians and common lawyers, which was fierce at the time of which we have just spoken—that is to say, at the beginning of the seventeenth century—was terminated eventually by the complete success of the common lawyers. Since the Revolution of 1688 the administration of equity in the Chancery Courts has been entirely in the hands of common lawyers. No ecclesiastic has occupied the office of Lord Chancellor or Lord Keeper since 1625, and from the Revolution onwards the civilian lawyers have been limited to the Admiralty, Probate, and Divorce Divisions, to the Military Court of the Marshall, the Ecclesiastical Courts of the Bishops in their various dioceses and of the Commissioners sitting at Whitehall, and the Parliamentary Court of the Steward.

In the modern system of the administration of the law in Chancery we find, therefore, a temper entirely different from that of the Star Chamber and the Council Board prevailing, and down to the year 1852 the grant of injunctions was limited by certain well-defined rules, the base or principle of which may be stated as being that recourse was to be had to an injunction only when no other effectual remedy was available to the plaintiff who has established his grievance in a Chancery court. In all cases for which the common law provided an effectual remedy the Chancery judges refrained from interposing their arbitrary authority. The general principle was thus stated by Lord Brougham :—

"The principle which, as I humbly conceive, ought, generally speaking, to be the guide of the court and to limit its discretion in granting injunctions, at least where no very special circumstances occur, is that only such restraint shall be imposed as may suffice to stop the mischief complained of."—Blackmore *v.* The Glamorganshire Canal Navigation, 1 Mylne and Keen, 185.

Coming to a narrower and, for our present purpose, more pointed statement of the principle, we have it formulated by Lord Lindley in the following terms :—

"The very first principle of injunction law is that *primâ facie* you do not obtain injunctions to restrain actionable wrongs for which damages are the proper remedy."—London and Blackwall Ry. *v.* Cross, Law. Rep., 31 Chanc. Div., p. 369.

The careful observation of this salutary rule would obviously preclude such mischievous results as we are now discussing, and with such authority as it is possible to cite for the rule one may without presumption speak of the existing and mischievous practice as being a lapse from the sound doctrine of the English law.

Let it be supposed, then, that by some means, either by a voluntary recurrence on the part of the courts to Lord Brougham's rule, or, failing that, by legislation, we were to arrive at a satisfactory settlement of this practice, is there any reason to think that the system would work badly and would unfairly prejudice the rights of a patentee? For the purpose of discussing this question, I will assume that recourse is had to Parliament, and that an enactment has been put upon the statute book which goes in one particular beyond the older practice of the Court of Chancery. I will assume, that is to say, that the enactment provides in effect : —

(1) That no perpetual injunction shall in any case be granted to restrain infringement of a patent right, but only an injunction to stand until further order ;

(2) That no injunction shall be granted to restrain infringement of a patent right unless it is proved to the satisfaction of the court that the mischievous result to the patentee from the infringement proved is such that he cannot obtain adequate relief in respect thereof from the defendant charged with the infringement.

What would be the result upon patent rights upon such a modification of the existing practice of the Courts?

(1) It would at once put an end to the blackmailing type of patent action. In recent years a practice has grown up of bringing patent actions against perfectly innocent infringers who have no sufficient interest in the dispute to make an effective defence. For example, let it be supposed that the article is some slight article of luxury, say playing cards. The patentee, if he were to attack the manufacturer direct, would have to encounter strenuous opposition, because the business in the hands of the manufacturer may very likely be a profitable business. But if he attacks some small retailer in a provincial town, whose interest in the trade is restricted to the selling of a half-dozen packs of cards in the course of a twelvemonth, he possesses this advantage

that it cannot be worth the defendant's while to be at the considerable expense of conducting a serious defence and attending in London for a lengthy trial, merely to preserve his liberty to deal in this particular commodity. The patentee's cards, or somebody else's, which cannot be attacked, will serve his purpose almost as well, and he therefore submits without a struggle. This puts the patentee in the advantageous position of being able to advertise that he has successfully defended his patent right, and is resolved so to do again, and in that way he may seriously impair or even destroy the trade of the rival manufacturer without ever giving him the chance of fairly fighting out the issue between them in a court of law. It is quite true that the Patents Act contains a provision for dealing with threats of patent actions, a provision which can be set in operation for the purpose of getting rid of certain classes of such threats. I, however, have purposely put a case to which this statutable provision does not apply, a case in which a great deal of mischief may be done under the cover of a patent for which the patentee cannot be made responsible. Now it is clear that if no injunction could be granted, but only damages in a case of that sort, the patentee would find that type of action a very unprofitable investment. The damages in such a case which he could recover would be trivial and insufficient to cover his costs. To that extent his patent right would no doubt be depreciated in value, but it is a loss against which those of us who do not happen to be patentees will certainly not be particularly anxious to protect the privileged class.

(2) Again, in a case such as the Badische action, it is clear that the patentees would have been wholly unable to destroy the British industry which they set themselves to attack. In fact, it is probable that the result of that action would in such a case have been more satisfactory to them as well as to the defendant company than in fact it was. If they could not have obtained an injunction they would have had to be content with damages, and although it may be presumed that in the circumstances of that case the damages would have been small, they still would have amounted to something. The patentees would have taken their share, and that probably something more than a fair share in the profits of the Lancashire dyeing industry, and the industry would have remained and flourished within this realm. The persons who really would have been injured by the proposed rule in that case are the dyers of Holland, who would have been deprived of the windfall which, in fact, so strangely came their way. That again is a result with which those of us, with whom the interests of the British industry are preponderant, will see no reason to find fault. The only case, I suppose, in which a hardship could arise, is that in which an inventor would be prevented by competition from developing the full resources of his invention. Put such a case as that of the invention of a new drug—saccharine for example. Assuming it to be a completely new departure, the public has to be educated up to a knowledge of its advantages. That is an expensive business, involving the outlay of time and money, and it may be upon a large scale. An inventor who is secure of his exclusive right to manufacture, can venture to expend, or may be in a position to induce other people to expend, a large sum of money for the purpose of advertisement. He may thus be enabled to make a market, and, if his monopoly is secure enough, to obtain complete reimbursement. This, of course, is the theory on which the monopoly is economically justified. We give to the patentee a limited monopoly in order that it may be worth his while thus to serve the public, not only by putting forward a barren proposal of improvement, but also by taking the pains to cultivate the success of his idea. It may well be that in a case such as that the patentee might be unable to obtain from an infringer the damages which would indemnify him for the expenditure which he had quite reasonably incurred on the faith of his patent grant. That an injunction should protect him in such a case is both just and expedient, and therefore the rule which I have borrowed from the Chancery reports is not so rigorous as the rule laid down in the Statute of Monopolies—that no injunction shall in any circumstances be issued in support of a patent right, but only that the court must exercise a real discretion and refuse the injunction unless some special circumstances are proved to warrant it. We should then, in the case now under discussion, arrive at a very useful distinction between two wholly different types of patent grants. Reference has already been made to one of these, that is to say, to blocking patents, which are designed not to be the basis of a new industry but to monopolise the road leading into an undeveloped region of industry in order that it may be explored at leisure by the patentee. A patent of that sort would not be protected by injunction, because

the patentee would not be able to show that infringement would inflict upon him any irreparable damage of which he was entitled to complain. The only expense to which he could point as entitling him to special consideration would be the cost of his experiments. Having regard to what we are told as to the dimensions of some of the German chemical research laboratories, it cannot be denied or even doubted that the expense so incurred in experimental work, even in working out these purely mischievous patents, must be considerable. But the court would understand that that preliminary expenditure was in the nature of speculation simply, and such as to entitle the inventor to no more public consideration than if he had made an unfortunate bull or bear bargain on the Stock Exchange. Expenditure upon the building up of a business comes into a totally different category. From it, if it succeeds, the public has derived advantage, and therefore the patentee in such a case is entitled to consideration as having undertaken a public service. If it does not succeed, in the sense, that is to say, of being a demonstrated failure, then the patentee is only in the position of other people who fail in business. It is not the function of the courts to convert such failures into artificial successes. Where, on the other hand, a patentee has made his grant the basis of a trade and has built up that trade by means of the reasonable expenditure of capital in establishing and extending it, the very object of the system of patent grants is being accomplished, and it is the province of the court to see that the machinery of the patent law is kept in working order for the promotion of that result. Hence the expediency, statutes and common law rules to the contrary notwithstanding, of lodging in the courts a discretionary power to give effect to the monopoly clauses of the grant in a proper case. The question still remains, would that purpose be effected by an injunction made, not perpetual, but till further order? It may, I think, be concluded that the limited injunction would fully meet the case. It has, for example, happened, and will doubtless happen again, that a patent, supported on the first occasion when brought to trial, has been disallowed on a subsequent occasion when the defence was supported by another defendant. This is obviously a thing which is likely enough to happen, especially under the modern system, which I have described, of bringing actions first against defendants who are unlikely to make a strenuous defence. Now, in a case of that sort, and in many other cases which might be suggested, it would be obviously an equitable and convenient course to allow the defendant against whom an injunction in the first place went to apply to have it discharged. It is not the object of the administration of our law to create such anomalies as that a manufacturer shall be restrained from practising an art because of the existence of a patent which has been proved to be invalid. It is obvious from this consideration that there is much to be said, even in the case of a meritorious patentee, for granting an injunction only subject to the condition that it may be discharged if cause is subsequently shown for discharging it. The full discussion of this somewhat technical subject would, however, demand much more time than it is possible to bestow upon it this evening, and therefore I will be satisfied, having shown this partial and *primâ facie* case in favour of the proposal to leave it at that, with the expression of my own opinion that upon the whole it would be a desirable reform.

The issues which I have hoped by this evening's discussion to raise are now before the Society. The proposal to establish a large manufacturing industry under the existing conditions of the aniline dye manufacture is one which raises not only the commercial questions of capitalisation and organisation, but also, in a very pressing form, the comparatively dormant question of a reform of the Patent Law. The comparative backwardness of our manufacture in this line, easily as it is explained by the indolence, supineness, and inaptitude for this class of industry of the British manufacturer, can nevertheless be fully explained only when the pitfalls of our Patent Law are also taken into account. This Society has a traditionary interest in the Patent Law. It was a principal promoter of the Great International Exhibition of 1851, which in its turn gave rise to the first reform of our Patent Law in 1852. This Society took a prominent part in the discussion which led up to the further reforms of 1883. It was not, I think, so well represented in the discussion which preceded the Act of 1907, and if I may venture an opinion the fact goes to show that the participation of this Society in such discussions is a matter of some importance. There is no doubt that both in 1852 and in 1883 substantial improvements were introduced into the administration of our Patent Law. That the Act of 1907 made for improvement is, as I venture to think, open to much question. It

complicated our system by the introduction of incongruous elements, chiefly from the German patent code, but it left untouched the mischiefs which destroyed the British manufacture of aniline dyes, and laid us open to the misunderstanding and reprisal in foreign countries without securing, so far as I can observe, any countervailing advantage for our own manufactures and manufacturers May I, in conclusion, be allowed to express the hope that when next the Patent Law engages the attention of the Legislature the Board of Trade will have the assistance of the Royal Society of Arts in considering the objects of reform and the means by which those objects may be accomplished?

DISCUSSION.

The Chairman (Dugald Clerk, D.Sc., F.R.S.), in opening the discussion, said he was quite at one with the author in the desire to improve the British Patent Law in such a way that industries should remain in Britain. He also agreed with him in the idea that the British manufacturer was by no means the foolish person which some people seemed to think, either from the scientific or the business point of view, but was fully able to take care of himself. In fact, the British manufacturer was able to build up trade in Great Britain which was sounder than any trade in the world, including Germany. It was true that Germany had some industries in which she excelled, but on the other hand Britain was supreme in many branches; for instance, in shipbuilding, in steam engines, in steam turbines, in some forms of gas and oil engines, in textile industries, and in textile machinery. Even in some of the heavy chemical industries and metallurgical industries Britain was extremely successful; but we, of course, should try to do everything possible, by aid of a Patent Law, to make things still more successful. On some points he differed from the author. The author's idea of dispensing with injunctions seemed to him (the speaker) to be such as would cause a very great depreciation in patent property all the world over. He quite agreed it might be desirable to correct a few cases of injustice by making an injunction withdrawable when necessary, but in the main he thought an injunction was the proper remedy. In his own opinion, it must not be forgotten that the Patent Law was devised to enable a man to get the benefits of his mental property. It was not devised to give him a present or a privilege, but it was devised to confirm him in the use of his own property, and in property which would not have existed but for his inventiveness and hard work. Too many people regarded patents as a privilege. The Patent Law was an endeavour to give the inventor protection against stealing from him his invention; and therefore, if people infringed, the appropriate remedy must, it seemed to him, be an injunction. No other remedy could possibly serve the purpose of confirming an inventor in the use of his own property. He had been very much interested in the famous Badische case, but he had to admit that he could not see the hardship. It was unfortunate that one industry in Britain was hampered by the decision in that case; but it had to be remembered that similar decisions were given in all civilised countries in the world. Every country in the world, if the patent was of a fundamental nature, would confirm the patentee in the use of his invention, and would give his claims a reading as wide as they justly could, and that seemed to be very proper. He did not see any fault in the judge's decision in the Badische case. He had had a very extensive experience in the law courts of England, America, France and Germany in studying and endeavouring to uphold the rights of inventors, and he must say that if the injunction was done away with the poor inventor would get nothing at all. Taking, for instance, the first Marconi case, one would have thought, looking at it as an outsider, that here was a very great invention, one of the wonders of the world, but when it came in the law courts able counsel attempted to prove that the invention was not a great invention but a very small departure from previous knowledge. In that case there was given a description of how magnetic induction passed through ether and air without wires, and one argument was that that magnetic induction had the same effect as a wireless wave. That was absurd, but the point had to be met very fully, and it had to be proved up to the hilt that the wireless wave was a different thing altogether. He could assure the audience that however fundamental an invention might be, so far as its effects on industry were concerned, it would be found that so many human minds had been busy in the last 150 years on things not very far removed from that very matter which had now become successful, that there was always a difficulty in establishing quite logically the exact point of departure the inventor had made. If the author's point was carried out, the matter could be so whittled down that no single inventor would ever be given the benefit of an injunction. He had been in many of the leading actions dealing with inventions in Britain in the course of the last twenty years, and he could not remember one that would have been allowed an injunction according to the author's method of argument. If a man had a certain intellectual property he was entitled to secure for himself as many variations of that property as he possibly could. He (the speaker) could see no harm in that at all. With regard to the prevalence of actions where the patentee was not brought into the action, but purchasers or sellers in some remote part of the country were sued instead, such actions were generally taken because the people who owned the patent had no property in the country, and it was necessary, therefore, to deal with some person who had property in the country; but where there had been an actual

inventor and an owner of a patent who could be sued, he had never known of a case where he was not sued.

Mr. Alan A. Campbell Swinton said he had always been impressed by a remark which had been made to him by a man whom he had always regarded as one of the greatest men he had ever had to do with, namely, the late Lord Armstrong, the original founder of Armstrong, Whitworth and Co. Lord Armstrong had been profoundly convinced that the whole Patent Law was wrong, and that patents should not be granted at all. He (the speaker) did not know to what extent Lord Armstrong was influenced by the fact that, alone among all the scientific men and scientific inventors, he was a first-class business man himself, but his lordship was always impressed with the idea that the Patent Law did much more to prevent invention than to foster it. Lord Armstrong always referred to one case in particular in that connection, namely, the wire-wound gun which was now in use in this country. Lord Armstrong and Mr. Brunel both had the idea of the wire gun at the same time, and they proceeded jointly to patent it. They discovered, however, that it had been patented about a fortnight previously. That fact held up the wire gun for fourteen years, as the original patentee was not capable of making a success of it, and was not prepared to come to any reasonable terms.

Mr. D. Leechman remarked that the author himself admitted that the circumstances attending the Levinstein invention were of a very singular nature. He (the speaker) did not remember any other case where an original patentee, holding a fairly broad patent, came up against an infringer, who was found to have infringed the patent, and yet was not able to tell how the infringer did the work. Those cases must be extremely rare, and it was a very grave consideration whether they could be specially legislated for. He understood the author to suggest that such an inventor as Levinstein should be allowed to carry out his invention without the permission of the original patentee, but he would venture to put the following case: Supposing he (the speaker) obtained a concession of a number of square miles of a rich mining country of a very hilly and intricate nature, and some man found a way to a particular spot in that country and discovered a valuable mine there and proposed to work it because he could find a way and he (the speaker) could not; would anybody dare to suggest for an instant that that man was entitled to work that mine without the speaker's consent? And yet it seemed to him that the conditions in the two cases were very similar. Then the author rather complained about the Germans taking out blocking patents, but the obvious reply to that was that British inventors could go and do the same. They had the same opportunities, and if they were not clever or keen enough to follow them up then it was their own fault, and not the Germans'. He agreed entirely with the author that the compulsory licence was a very useful and proper remedy under certain conditions, and that the means for providing compulsory licences should be much easier than they were at present. He had suggested on a previous occasion that compulsory licences should be granted by the Comptroller. It was rather extraordinary that the Comptroller could revoke a patent, but could not grant a compulsory licence. There should also be opportunities given to the court to grant compulsory licences. With regard to the education of the manufacturer, his experience was that if a new industry was started a whole lot of people rushed into it who had failed in other industries, and looked very shyly at the men who really knew—the scientific men; but that sort of thing was passing away. When an industry entered into the second generation, the manufacturers who were carrying it on knew as much about it as anybody; they had been taught the business and properly trained for it, and had a good appreciation of both the commercial and scientific sides. He thought the author looked at the matter very much from the manufacturer's point of view, as distinct from the patentee's. He did not think that was right, but considered that it should be looked at from both points of views. If the injunction was to be abolished, it would mean it would have to be taken out of the Letters Patent to begin with. Therefore that would be altering the consideration which the country paid for being uniform as to those inventions. The more the consideration was reduced the fewer the inventions, and the country would suffer in consequence. The patentee of the present day was having a very bad time of it indeed. It had only to be remembered in that connection that about half of the applications for patents were never completed. Of those which were completed not one in ten had even the first renewal fee paid on it. If inventors were having such a very good time of it, and were the blackmailing bullies that the author seemed to suggest, those figures would not be true.

Mr. G. G. M. Hardingham said the paper had not dealt with the Patent Laws in the way in which he expected it would. One difficulty, for instance, under the present system was the excessive cost, and a second was as to the term, which in many cases was too short. He did not see why there should be a shorter term in this country than the rest of the principal countries, where it was very nearly sixteen years, as against fourteen years here. With regard to cost, a German patent cost £17, an English patent £7, and a United States patent 7*s*. If the United States could grant a patent for that small sum why could not Great Britain? Then, again, the United States search was far superior to our own; it embraced not only the specifications of United

States patents but of British patents and all the publications which were filed in the Patent Office there. The search in this country was very misleading. A British inventor thought that if he passed through the examination stage of the English Patent Office his invention was new, whereas that was by no means necessarily the case.

Mr. Walter F. Reid said he had learnt one thing from the paper, namely, that a judge after once granting an injunction had no power to get rid of it again. It seemed to him that was a difficulty which ought to be got over if possible by some alteration of the law, although personally he was a little doubtful about alterations of the law, as somehow or another they always turned out to be to the disadvantage of the inventor instead of to his advantage. He quite agreed with Mr. Hardingham's remarks. It was not fair that the State should declare a big profit out of the produce of the best brains of the country. There ought to be a material reduction in the patent fees, and the present time was a very favourable one to press for it. Two names had been mentioned by Mr. Swinton in connection with the wire gun, but the man whom he (the speaker) always understood to be the inventor of that gun was Mr. Longridge. It was a very curious thing that ideas did not originate always in one mind alone but in many, and that ideas seemed to come in crops, all at once. He himself had possessed a master patent. He had a patent for making smokeless powder throughout the world. He thought he had really invented it, but he had come across a little pamphlet in German in the British Museum, which had not even been cut, in which he found that a German botanist had carried out the same operation as he had subsequently found out himself. With regard to the remarks of Sir Bernhard Samuelson, he would deprecate very much attaching any importance to them at the present time. Sir Bernhard was a very great pioneer in education, but the conditions in 1881, when he made those remarks, were totally different from what they were at the present time. From a very wide experience in the matter, he (the speaker) could say that there was as much chemical ability in this country at present as was required for our industries. The author had said that the judges had either forgotten to exercise their discretion in the matter of granting injunctions, or that they had long ceased to exercise any personal discretion in the exercise of the jurisdiction to grant injunctions. But that was not the fault of the law; if the judges did not carry out the law, it was for the public to ask them to.

The Author, in reply, said that both the Chairman and Mr. Leechman had laboured the point that a patent ought to be treated as being a method of establishing and vindicating property of an intellectual kind; and that intellectual property ought, as much as physical property, to be the subject of personal rights which should be defended in the one case as effectually as in the other. That opened up an extremely large subject which it would be very interesting to debate at length, but he would call attention to one aspect of it. Physical property differed from intellectual property in the important particular that, with the exception of land, physical property could be multiplied to the extent to which it was required to supply our necessities; but intellectual property could not be multiplied. Intellectual property was in the essential nature of a monopoly, and one could not assign a piece of intellectual property to one man and say, "This is yours," without preventing another man from exercising his intelligence for the sake of acquiring the same or a similar property. Property which, in the nature of it, was a monopoly, must be subject to different proprietary rules from property which was not in the nature of an essential monopoly. That distinction was observed in all systems of law. There were in all systems of law different rules with regard to real property which was in the nature of a monopoly, because it could not be indefinitely multiplied, and commodities which could be indefinitely multiplied; and distinctions of that sort were inevitable in any system of jurisprudence. A distinction of that sort arose to which, he thought, neither the Chairman nor Mr. Leechman had attended. There must be such a distinction between intellectual property and property which could be indefinitely multiplied There must be a wide distinction which put the laws relating to the one necessarily in a different category from the laws relating to the other. He thought intellectual property might, within limits and under certain restrictions, very properly, and with advantage to the whole community, be made the subject of personal rights, but those personal rights must be defined and shaped with a view to the interests of the community, which preponderated over any personal interests. The consequence was that in some of the most valuable intellectual results no property at all ever had been or was ever likely to be granted. With regard to Mr. Swinton's remarks as to whether patents did not on the whole hinder the development of our industries, there was no doubt that in certain cases patents had tended very seriously to hamper industries. If those cases were the rule Patent Law would be a mistake, but those cases were in fact not the rule, and he thought it might be said with great confidence that those mischievous effects were all capable of being eliminated by a properly adjusted and well administered system of Patent Law. He thought nobody could seriously doubt for a moment, looking at the way in which our industries in fact are rooted in patent grants, that the Patent Law worked extremely advantageously upon the whole.

THE GROWING OF SPRING WHEAT.*

The plans made by farmers last autumn for increasing the area under wheat could not in many cases be carried out owing to the almost continuous wet weather experienced during the last months of the year. Attention is therefore now being directed to the possibilities of spring-sown wheat. The relationship between autumn and spring varieties of wheat may be briefly described.

The widespread cultivation of wheat, coupled with the well-known tendency of plants to vary with their surroundings, has led to the existence of a large number of more or less distinct types and varieties. Wheats of dry countries and of countries exposed to severe winds commonly have narrow leaves, pliant straw, bearded ears and velvety chaff, which enable them to resist drought and wind. Wheats of moist climates have broader leaves, which admit of more rapid transpiration, or passing off into the air of water taken up by the roots.

In recent years the attention devoted to crossing and selection of wheats has still further increased the number of varieties suited to particular requirements.

So far as the farmer is concerned the most important points are yield, strength, and power of resisting drought and disease. Each farmer should therefore consider which variety or varieties will best suit his own locality, and grow that which will yield him most profit. In Russia and Canada, where the winter is long and severe and the summer is a period of almost uninterrupted light, quickly-maturing spring wheats of the highest quality have been produced. When grown in this country such varieties usually maintain their characteristic early maturity, low yield and high quality.

One of the best known of Canadian wheats is Red Fife, which has been grown as a spring wheat in this country for many years. Its yield, however, is low, the heaviest crops not usually being more than 3 to 4 quarters per acre, although in a few districts yields approaching those of Squarehead's Master have been obtained. There are a number of strains of Red Fife, some of which are more productive than others. One of them, the Marquis, has proved the best of the Fifes grown in Manitoba, and is now on sale in this country. The Department of Agriculture and Technical Instruction for Ireland have also obtained, by selection, a strain of Red Fife which gives satisfactory returns in Ireland. The introduction, some few years ago, of Burgoyne's Fife (a cross between Red Fife and Essex Rough Chaff, effected by Professor Biffen at Cambridge) marked a distinct advance on the productive capacity of ordinary Red Fife. This variety still retains the fine milling qualities and early maturity of Red Fife, and is a distinctly better yielder, though not equal in this respect to standard varieties of English autumn wheats.

As regards the period required to mature, there is, in reality, no sharp distinction between autumn and spring wheats. In a favourable year, spring-sown autumn wheat will ripen satisfactorily in the earlier parts of England.

It is well known that cereals brought from an early district to a late district will ripen earlier than the produce of locally-grown seed. Hence, if it is desired to sow autumn wheat in spring, it is desirable that the seed should be obtained from as early a district as possible, and be sown before the end of February. The general unreliability of autumn wheats when sown in spring, however, has led to their almost total abandonment in favour of spring varieties, and at the present time chief reliance is placed upon certain wheats brought out by Vilmorin of Paris. These, whether sown in autumn or in spring, almost invariably reach maturity a week or two before the standard English wheats. As regard both yield and quality, they are not far short of ordinary autumn wheats. Other varieties of spring wheats, notably "April or Spring Bearded," have long been grown in England, but these older sorts are now rarely met with.

Soil.

Any soil on which autumn-sown wheat will thrive will usually grow spring wheat satisfactorily, provided it is possible to obtain a fine, mellow seed-bed which can be made fairly firm below. All cultural operations, therefore, should be directed towards this end, the object being to secure quick, uniform germination and growth, since wheat sown in spring has a comparatively short period of growth. The best results will usually be obtained after a corn or root crop. Drilling is usually to be preferred to broad-casting. After ploughing, if the furrow is fresh and loosely packed, the Cambridge or ring roller may be run over to consolidate the land, after which the harrows should be freely used so as still further to consolidate the bottom soil while leaving the top inch or two loose and fine. It will usually be found advisable to postpone rolling till the plant is up, for, in addition to further consolidating the soil and smoothing the surface, late rolling will have the effect of promoting tillering, in which spring wheats are deficient.

Manuring.

Unless the soil is highly fertile it will as a rule be advisable to apply some artificial manure, with the two-fold object of encouraging growth and hastening maturity. A dressing of ¾ to 1 cwt. of sulphate of ammonia and 2 or 3 cwt. of superphosphate per acre will usually answer the purpose. The manure should be applied before the final harrowing, or the superphosphate may be applied when harrowing after sowing, and 1 to 1½ cwt. of nitrate of soda may be top-dressed in April. If the spring is wet, and the young wheat is yellow and backward towards the end of April, nitrate of soda will prove most useful.

* Special leaflet issued by the Board of Agriculture and Fisheries.

A SIMPLE METHOD OF TESTING CORN FOR SEED.

A practical and simple way for testing the germinating power of corn intended for seed is given in an American journal, *The Outlook*.

The value of such a reliable test, which can be mastered by any intelligent pupil in a rural school, should be obvious to the British farmer. The test is made in the following manner: A piece of heavy sheeting, 5 ft. long by 9 ins. wide, is marked off into a dozen or more squares about 2½ ins. square, running through the middle of the cloth. These squares are numbered, say, from one to twelve. An equal number of ears of corn are selected for the test and numbered to correspond with the cloth. The cloth is thoroughly moistened and spread out in front of the ears of corn. Six grains of corn are taken from ear No. 1 and placed on the square of same number, germ side up, with the tips of the grain all pointing in the same direction. In the same manner six other grains taken from ear No. 2 are placed on square No. 2, and so on until all the squares are filled. When this has been done, the cloth is again moistened by sprinkling, and then carefully rolled up so that none of the grains will be displaced. A string is then tied round the centre of the roll, just tight enough to keep the grains of corn in place.

This done, the bundle is placed in a pail or bucket filled with warm water; it is set on end with the tips, or small ends of the grain, pointing downwards. Old newspapers are then wrapped round the pail in order to retain the heat. In from three to twelve hours the newspapers should be removed, the water poured off, and the pail again covered with newspapers. It should then be placed in a room, which must not get too cold at night or be allowed to freeze.

At the end of seven days, when the grains have begun to sprout, it will be an easy matter to tell which ears are fit for seed or not. It will be found in this way that some of the ears are dead, whilst others are too weak to be used for seed.

No one can select good seed by merely looking at it; he may be able to tell that some will not grow, but he can never be certain that the seed which he has selected will germinate or come to perfection.

The value of good seed is of vital importance to the nation, especially at the present time, and certainly a knowledge of how to procure it should be taught to our rural population. If the farm lad has work of interest and responsibility to do in school—work which he can see is directly related to his vocation—he is far more likely to remain on the land than to flock to the town, as is too often the case at the present time.

PRODUCTION OF QUININE IN ITALY.

A report from the director of government monopolies to the Minister of Finance gives some interesting figures concerning the manufacture of quinine and products containing that drug, at the pharmaceutical laboratories belonging to the State in Italy during the financial year 1912–13.

From this it appears that the gross receipts from this source amounted to 2,899,190·37 lire (£115,967), working expenses 1,964,916·19 lire (£78,598), leaving a net return of 934,230·18 lire (£37,369). This shows an increase of 14,467·74 lire (£578) in favour of last year's working as compared with that of 1911–12. This profit of 934,230·18 lire has been (as required by law) paid into a fund for preventing the spread of, and for relieving cases of malarial fever (*Sussidi per combattere la malaria*). Of this amount, quinine and preparations containing the drug to the value of 142,318·62 lire (£56,916) were supplied by the government laboratories, in the proportion of 98,578·80 lire, to the various communes in the Basilica, Calabria and Sardinia, and 43,739·82 lire to those in other districts throughout the kingdom which suffer from this cause.

The balance has been paid in cash in subventions to the various local authorities, the Red Cross Society of Italy for their anti-malarial campaign, as well as to many charitable institutions, and other bodies in the districts affected by this scourge.

The total output of the government laboratories for the financial year 1912–13 amounted to 71,905 kilogrammes (158,550 lbs.), of which 36,728 kilogrammes (80,985 lbs.) were quinine, and 35,177 kilogrammes (77,565 lbs.) products containing quinine. This is an increase of 1,128 kilogrammes (2,587 lbs.), and 319 kilogrammes (703 lbs.) respectively on the production of the previous year.

The total quantity of quinine sold to the public in Italy last year was 35,781 kilogrammes (78,804 lbs.). The number of places of sale was 31,602, of which 30,485 were sellers of tobacco and other articles of government monopoly.

The exports amounted to 13,223 kilogrammes (29,157 lbs.), Greece and Bulgaria being the principal destinations.

The average consumption last year, in Italy, of quinine manufactured by the State was 569 grammes (36·87 grains) per 1,000 of population, as compared with 545 grammes (35·32 grains) of the previous one.

The cost of production for all kinds of preparations and tabloids (except tannate of quinine) was 1·42 lire per kilogramme less than that of the previous year, and this in spite of the increase in the prices of the raw material.

ARTS AND CRAFTS.

War Memorials and Rolls of Honour.—An exhibition of designs for war memorials and rolls of honour is at the present moment a very practical and a very wise idea. There are not only numerous societies, parishes, institutions, and the like, whose members wish for some more or less permanent record of the names of those connected with them who are serving their country in the Army and Navy, but also many people who are faced with the difficulty

of choosing a suitable memorial to those who have fallen. It has hitherto been too much the habit here in England on such occasions for the donors of memorials to go to some firm whose name they happen to have heard of quite casually, and to take with more or less (usually more) docility what they choose to offer. This has no doubt answered admirably sometimes. We all know that some manufacturers take a pride in producing nothing but the best, but too often the result has left a good deal to be desired. That attitude of mind is by no means a thing of the past. Anyone who reads, for instance, the accounts of new stained-glass windows put into churches will be surprised to see what an unusual thing it is to find any mention of the firm or of the artist responsible for their design. Apparently the popular idea is that a stained-glass window *is* a stained-glass window, no matter whether it be good or bad. The parish may be interested in the fact that it cost so much per square foot, but they do not expect anyone to care who produced it. This is rather hard, both on artists and on those manufacturers who have a care for the artistic quality of their work, and it is a point of view which one hopes that people are outgrowing, however gradually. Meanwhile the exhibition at the Fine Art Society's galleries is an attempt to put those members of the public who desire memorials into touch with artists who are ready and willing to provide them. The collection is not large, and, of necessity, consists mainly of small mural tablets and illuminated rolls of honour, but there are a few photographs and sketches of larger and more important work. The memorial tablets shown are not for the most part specially designed for this exhibition, but are intended to indicate the kind of work which the artists submitting them are prepared to undertake. The memorial tablet by Miss Jessie Bayes, on gilded wood with an inscription from the Russian Liturgy, is very satisfactory, and Miss E. M. Rope's plaster design of angels censing, with the inscription, "Praise God for the life of ——," is full of feeling. The rolls of honour include an interesting sketch-design with a soldier on one side, a sailor on the other, and a recording angel in the lunette above by Mr. Byam Shaw; a rough but well-spaced sketch by Mr. Percy Smith; an unusual suggestion, half modern, half on the lines of an old book illumination, by Mr. Russell Flint; fine examples of script and illumination by Mr. Allan F. Vigers and Mr. Graily Hewitt; and a really charming opening page of an illuminated roll of honour decorated with an allover scroll pattern by Mrs. Louise Powell. If the exhibition only serves to make the unfortunately all too numerous people whose thoughts are now turned towards the erection of memorials realise the possibility of having something really artistic, and insist upon getting it, it will have answered a very useful purpose and have earned the gratitude of posterity, besides helping artists, who are, as is well known, by no means overwhelmed with work at present.

Lace.—Lacemaking is a craft which is very much in people's minds to-day. For some years past English women have been taking an interest in it, and in many English counties (not to mention Ireland) a quite remarkable revival of the art has taken place. On the other hand, the devastation of Belgium, and the quantities of Belgian lace which have come over to England, have reminded us very forcibly that our own hand-made lace industry is not only younger but smaller and more exotic than that of the gallant little country on the other side of the Channel. It is, therefore, a happy idea on the part of the committee of the Women's International Art Club (who are dividing the gate-money of their sixteenth annual exhibition now being held at the Grafton Galleries between the Queen's Work for Women Fund and the Belgian Relief Fund) to include amongst their exhibits a collection of lace. The co-operation of Count Lalaing and of M. Paul Lambotte, Directeur des Beaux-Arts, Brussels, has been obtained, and a great deal of fine lace has been brought together, in which are to be found some very good specimens of old Flemish lace. The show includes a certain amount of modern Belgian work, some of which is for sale, and samples of lace which Belgian workers are willing to execute at very moderate prices. This modern work is quite good of its kind, and, if the exhibition had consisted of nothing else, would probably have attracted its share of attention. The scarf in *point de flandre* lent by the Société des Arts de la Femme, for instance, is a really fine and beautiful piece of modern workmanship, and there are other very interesting examples. It must be admitted, however, that the main attraction of the exhibition lies in the older work, of which specimens are shown of dates ranging from the fourteenth to the eighteenth centuries (the earliest being, of course, *tela tirata* and not lace proper), and coming not only from Belgium but also from Italy, France, England, and Holland. No one who cares for lace could fail to be interested in the show. The exhibits are not all equally good, but the best of them are really remarkable. Beautiful Belgian lace is lent by Madame Moons, Madame de la Croix, Madame Rothschild, and others. Mrs. Herbert Cohen sends a very choice little collection of examples, mainly Italian and Belgian; Mr. Samuel Chick some very interesting and fine Angleterre lace, as well as specimens of Mechlin, Brussels, and Lille. Buckingham, Honiton, and Irish crochet are all represented, as well as the many varieties of Belgian and Italian work. Lovers of the older and rather more severe types of lace will, however, consider that the historical collection shown by Mrs. Hungerford Pollen is the crowning point of the exhibition. Every piece has some point of interest, and the lace is so beautifully kept and shown that it is a treat to look at it. The exhibition cannot but give pleasure to all those interested in lace from whatever point of view, and will repay careful study by those in any way concerned with the production of hand-made lace.

Women's Craftwork.—Exhibitions of the various societies of women artists are not as a rule, for some unknown reason, the best places for finding the most accomplished of the work executed by English craftswomen, and the current exhibitions of the Women's International Art Club and the Society of Women Artists form no exception to the general rule. On the other hand, they both include a certain amount of creditable craftwork. At the Grafton Gallery, Mrs. Phœbe Stabler exhibits some of her charming little glazed pottery statuettes, Miss Isabel Hope shows some tasteful silverwork, and Miss Ethel Virtue has a case of jewellery, some of which is rather fresh in design. On the whole, however, the jewellery both here and at Suffolk Street, where good work by Miss Rimington and others is to be seen, tends to be all very much of one type, while the prices asked, which are far lower than they were a few years ago, suggest that it must be very difficult, if not impossible, nowadays for a woman to earn her living at this kind of work. The most interesting embroidery at the Grafton Galleries is the coarse brightly-coloured work in wools by Madame Ghysbrecht and others which appears to represent a school. The workers are undoubtedly striving after something, but the results so far achieved can hardly be described as satisfactory. They suggest a kind of compromise between futurism and old-fashioned woolwork, which is by no means beautiful. There is no equally startling needlework at Suffolk Street, nor any very wonderful craftsmanship, but the work there is interesting because none of it is of exactly the type which is at the present moment so popular in the Schools of Art, at any rate in London. There are several examples of appliqué work, including a piece of leather appliqué on a coarse canvas material by Miss Edith A. J. Wright, which, if not quite satisfactory, gives promise of good results later on, and some pretty little embroidered landscapes. The needlework versions of pictures by Romney and Sir Joshua Reynolds, again, are not conspicuously successful. That is hardly to be wondered at, for needlewomen who want to copy figurework are better advised when they seek their inspiration from the flatter and more conventional work of the earlier masters. Mrs. George Looseley's vellum-covered boxes, decorated with tooling and onlaid leather, are dainty and tasteful, though one feels that the fastenings ought to be rather better. On the whole, however, neither exhibition can be taken as representing the best that is being done by women in the field of the artistic crafts.

CORRESPONDENCE.

THE DECORATIVE TEXTILE INDUSTRIES AND THE DESIGNER'S RELATION THERETO.

I fear that this eternal warring of the "trade" with the "schools" in reference to textile designing is on a par with the quarrel which commercial men wage at intervals with elementary education. It would be convenient [for the business house] if the primary school, at the expense of the State, would turn out clerks meet for their prospective employers' service. But that is not the function of the primary school. So, also, the textile producer would have reason to rub his hands if, by simply going to the School of Art and holding up the alluring bait of £5 a week, he could get the perfect article which he required.

The State, however, cannot be expected thus to subsidise any branch of commerce or industry. The School of Art is not a textile factory, and the Art master has a score of other things to teach besides design. If the producer wants men well versed in all the ways of the producing machine let him train them himself, and if, when he has finished, he is satisfied, let him keep away from the School of Art altogether. His perpetual jibing at the schools arouses the suspicion that he cannot do without them. They can give his designers something which he and his workshop cannot, and he professes disgust that they do not also give that which he with his technical knowledge and facilities can and ought to give.

The student can get in the School of Art that instruction which, when supplemented by the practical training of the workshop, will result in his being efficient both practically and artistically. Just as the Art teacher trained in the schools is satisfied with a small salary until he has gained practical experience in teaching, so the design student would, I imagine, be satisfied with something less than £5 a week until he had acquired the technical finish to his artistic training of the Art School.

If the producing firms wish for schools which shall undertake both the artistic and technical branches of designing let them bear the cost or, at least, share it. Then certain schools, as centres for fixed areas, could be provided with the weaving and printing machinery necessary for the particular work, and the other schools, freed from constant criticism, could continue their excellent task of providing, in Mr. Eva's words, "a sound basis for all branches of Art."

R. E. GREEN.

OBITUARY.

WILLIAM WILLETT.—The death of Mr. William Willett took place on the 5th inst. at his residence in Chislehurst, at the age of fifty-eight. He was the head of the well-known firm of builders that bears his name, and is familiar to the public as the builder of some of the most beautiful houses in London. The reputation of the firm was first established by Mr. Willett's father, who only died in 1913, but it was greatly enhanced under the direction of the son, who was remarkable alike for his gifts as a builder and designer and as a business man. A large number of houses have been erected

by the firm, notably in the Kensington and South Hampstead districts, and they are usually remarkable for their artistic appearance and convenient planning.

Apart from his work as a builder, Mr. Willett's name was well-known in connection with his "Daylight Saving Bill."

Mr. Willett was elected a member of the Royal Society of Arts in 1893.

GENERAL NOTES.

Manufacture of Toys in Spain.—It has become apparent in Spain in recent years that the manufacture of toys can be made a lucrative industry on account of the steady demand, with the result that at present there are at least 400 Spanish manufacturers of importance supplying toys for domestic use and for export. The toy industry has made such pronounced progress that a national exhibition of toys was recently held in Barcelona, and it was largely patronised by the toy-makers in the neighbourhood, as well as throughout the Peninsula. Among the articles chiefly exhibited were turned wooden goods, including nine-pins, small furniture, besides croquet sets and wagons; metal goods, such as soldiers, small table services, trains, mechanical toys, guns, and pistols; paper goods, theatres with figures, marionette shows, and leather goods, comprising footballs and stuffed imitation animals, such as horses, donkeys, and dogs. The well-known brown bears are replaced by Spanish bulls. Special attention is given to the production of fine dolls of wax, papier-mâché, and china, many of which are dressed in national costumes. It may be noted, however, that highly-developed, self-propelled, and electrical toys are not much in evidence, and there appears to be a market in Spain for the introduction of articles of this kind of a good quality.

British Columbia Red Cedar.—British Columbia is regarded as the last stand of red cedar in North America, and it is predicted by lumbermen that within the next few years hundreds of new shingle mills will be established there to participate in the profits to be derived from the manufacture of cedar shingles, and that British Columbia will have almost the exclusive market of the continent for its red cedar lumber and shingles. Cedar logs and shingle bolts are not exported, except from Crown lands, and the prohibition will result in more mills coming to the province, as the product must be manufactured there. More than half of the shingles produced are exported to the United States, and as there still remains a plentiful supply of cedar timber in British Columbia, the industry promises to increase in importance and to become ultimately very profitable.

The Production of Geranium Oil.—The plant from whose stems the geranium oil of commerce is extracted was brought from South Africa to France about 1690. It was first cultivated on the Riviera, in the neighbourhood of Grasse, about 1847 for the production of geranium oil, and was introduced from France into Algeria about 1848. It is claimed that the quality of the geranium oil produced in the south of France is superior to that made elsewhere, but it can be produced more economically in Algeria. Owing to frost the plant has to be planted annually in France, and intensive cultivation, involving a considerable use of manure and watering, is necessary to secure an annual cutting. In Algeria the plant generally lives five to six years longer, and three annual cuttings can be made. Geranium oil produced in Spain is of good quality, and the geranium plant is cultivated in Valencia and Almeria. Owing to the economy of production, due to favourable climatic conditions, the most important producers of geranium oil at present are Algeria and the Island of Réunion. Geranium oil is a high-class perfume, but it has only a limited market, and prices have been affected by over production, and especially by the sale of cheap artificial perfumes. Geranium oils are liable to adulteration with fatty oils, and with the oils of turpentine and cedar-wood.

The Use of Cork Dust in Spanish Fruit Packing.—While a good deal of cork dust is used in the Province of Malaga and elsewhere in Spain, the city of Almeria consumes more of it than any other place in the country for its enormous exports of about 2,000,000 barrels of grapes per annum. Each barrel requires over 8 lbs. of cork dust, and each half barrel, of which usually only some 20,000 are exported, half as much. Altogether, including other fruit as well as grapes, about 12,000 tons of cork dust are used at Almeria alone, besides 200 tons in the Province of Malaga. As the quantity of dust made in Malaga is not sufficient for the requirements, large supplies are received in Almeria from Algeciras, San Roque, and other places in Andalusia, and from San Feliu de Guixols and elsewhere in Catalonia. Experiments are now being made on a large scale in shipping tomatoes, bananas, etc., from the Canary Islands packed in cork dust, and several consignments of dust for that purpose have lately been sent there from Malaga. The dust for the above purpose is cut finer than for grapes, for which it is ground a little smaller than grains of wheat. It is prepared for both uses by grinding the cork or cork trimmings between revolving stones, as in old-fashioned grain mills.

Weights and Measures Computor.—Mr. F. Seaton-Snowdon, of 22, Henrietta Street, W.C., has recently patented a "computor" which converts the value of goods offered in the currency and measures of one country in the correlative equivalent of the coinage and measures of another

country. The instrument closely resembles the familiar date indicator, and is equally simple in its manipulation, it being so arranged that by the mere movement of one of two handles the cost in pounds, shillings, and pence of an English lb., gallon or foot can be instantly and accurately read off in the equivalent units of any foreign measure of weight, capacity, or length, together with its value in the coinage of its country. The range of the instrument, as designed for use by those whose calculations have to be based on British coinage, is from ½*d.* to 10*s.* per lb., gallon or foot, but "spools" on which the figures are printed are in course of preparation, and will shortly be available for use by those who prefer to take as their value basis the currency of their own country. The "spools" are interchangeable, and a set of them can thus be used, as required, with the same instrument. The instrument is quite portable, the base being only some 3 ins. by 9 ins., and the price is 31*s.* 6*d.*

THE BRITISH ASSOCIATION.—The Council of the British Association, after consultation with the local executive committee at Manchester, has decided that the annual meeting of the Association shall take place in that city, as arranged, in September next. Both the committee and the Council have felt that it would be inexpedient, under present conditions, to offer the elaborate local hospitality, in the form of social and other arrangements, which has been extended to the Association on former occasions. The committee, however, expressed its desire that "the long continuity of the yearly meetings should not be broken," and stated that it would "prefer that the meeting should be held although restricted to its more purely scientific functions."

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock (except where otherwise announced):—

MARCH 17. — H. M. THORNTON, "The Industrial Uses of Coal Gas." SIR CORBET WOODALL, D.Sc., M.Inst.C.E., Governor of the Gas Light and Coke Company, will preside.

MARCH 24, at 5.30 p.m.* —LADY LUGARD, "The Work of the War Refugees' Committee." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, will preside.

APRIL 14. — T. THORNE BAKER, "The Industrial Uses of Radium."

APRIL 21.—MORETON FREWEN, "Profit and Loss in Our Sea Fisheries."

APRIL 28.—A. S. E. ACKERMANN, B.Sc., Assoc. M.Inst.C.E., "The Utilisation of Solar Energy."

* The hour of this meeting has been changed from 4.30 p.m. to 5.30 p.m.

MAY 5. — AUGUSTUS VERNON HARCOURT, D.C.L., LL.D., D.Sc., F.R.S., "On an Economical and Smokeless Grate, and on the Measurement of the Efficiency of Open Grates."

INDIAN SECTION.

Thursday afternoons:—

MARCH 18, at 4.30 p.m. —LIEUT.-COLONEL A. C. YATE, I.A. (retired), "The Indian Army." The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., will preside.

APRIL 15, at 5 p.m. — PERCEVAL LANDON, "Basra and the Shatt-ul-Arab." The RIGHT HON. EARL CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., will preside.

MAY 13, at 4.30 p.m. —M. M. S. GUBBAY, I.C.S., "Indian Trade and the War."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

MAY 4.—S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials." The HON. SIR GEORGE H. PERLEY, K.C.M.G., Acting High Commissioner for Canada, will preside.

Dates to be hereafter announced:—

C. H. SHERRILL, "Ancient Stained Glass."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

M. H. BAILLIE SCOTT, "House Building: Past and Present." Three Lectures.

Syllabus.

LECTURE I.—MARCH 15.—*House Building, Past and Present.* The nature of the building art—The modern conception of building and architecture—The utilitarian spirit in house building—The house necessarily a work of art, good or bad—As such has degenerated in modern times—The old house still the best—Architecture a dangerous term, and why—No art is degraded because it is useful—The fallacy of pure art—No pure art in nature—Art must cling to life and express itself in the service of life.

LECTURE II.—MARCH 22.—*Houses in the Past in this Country.* Three main periods: (1) The craftsman or mediæval period, when the art of building flourished; (2) The scholar, or Renaissance period, when the building art became "tongue-tied by authority"; (3) The shopkeeper, or commercial period—The distinguishing features of the three periods set forth as an allegory—The trades guilds—The spirit and methods of the old craftsmen—The scholar spirit—The commercial spirit.

LECTURE III. — MARCH 29. — *Houses of the Present.* The average house of the craftsman period adorned the world—The average modern house disfigures the world—Normal modern building a disease rather than an art—The causes and cure of this disease—Difficulties of the architect—Building by-laws—The qualities of various types of houses discussed—An ideal house described.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.
April 26, May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 15. ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. M. H. Baillie Scott, "House Building: Past and Present." (Lecture I.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Dr. A. M. W. Downing, "The Determination of Easter Day."

Surveyors' Institution, 12, Great George-street, S.W., 7 p.m. Mr. A. J. Carpenter, "Some Points on the Insurance of Buildings against Fire."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. J. Williams, "English Monuments."

TUESDAY, MARCH 16...Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Mr. E. Crammond, "On the Cost of the War."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Discussion on "The Marking and Rating of Lamps and the Best Methods of Specifying their Illuminating Value."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. G. Frazer, "The Belief in Immortality among the Polynesians." (Lecture I.)

Engineers and Shipbuilders in Scotland, Institution of, 39, Elmbank-crescent, Glasgow, 8 p.m.

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. R. B. Fishenden, "Machine Photogravure."

WEDNESDAY, MARCH 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. H. M. Thornton, "The Industrial Uses of Coal Gas."

Meteorological Society, at the Surveyors' Institution, Great George-street, S.W., 7.30 p.m. Dr. W. G. Duffield, "The Meteorology of the Sun."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 7.45 p.m. (Students' Section.) Mr. W. H. Date, "Some Experiments on the Induction Generator."

(Local Section.) The University, Birmingham, 7.30 p.m. Mr. W. R. Cooper, "Electric Cooking, mainly from the Consumer's Point of View."

Microscopical Society, 20, Hanover square, W., 8 p.m. 1. Mr. E. J. Sheppard, "A New Mitotic Structure Disclosed as the Result of New Technique." 2. Mr. G. H. Wailes, "Notes on the Structure of Tests of Freshwater Rhizopoda."

Literature, Royal Society of, 20, Hanover-square, W., 5.15 p.m. Professor A. C. Benson, "George Gissing."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 8 p.m. Annual Meeting.

THURSDAY, MARCH 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Lieut.-Colonel A. C. Yate, "The Indian Army."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W, 5 p.m. 1. Mr. W. M. Webb, "Hollow-shafted Feathers." 2. Messrs. J. A. Wheldon and W. G. Travis, "The Lichens of South Lancashire." 3. Mr. E. J. Bedford, "Coloured Drawings and Lantern-slides of Thirty-six British Orchids." 4. Dr. A. B. Rendle, "A Few Australian Plants."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Mr. A. E. Dunstan, "The relation between viscosity and chemical constitution. Part IX.—The viscosity and fluidity of the aliphatic acids." 2. Messrs. J. C. Irvine, A. W. Fyfe, and T. P. Hogg "Methylated derivatives of a new form of glucose." 3. Mr. N. P. Campbell, "Velocity of crystallisation from aqueous solutions." 4. Messrs. A. Senier and R. B. Forster, "Studies in phototropy and thermotropy. Part VI.—Polymorphic vanillidenearylamines produced by trituration and by the influence of actinic light." 5. Messrs. J. A. Meads and F. S. Kipping, "Organic derivatives of silicon. Part XXIII.—Further experiments on the so-called siliconic acids."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. Strahan, "The Form and Structure of the London Basin." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. G. Lamley, "The Western Highlands."

Historical Society, 22, Russell-square, W.C., 5 p.m. Messrs. H. Jenkinson and H. Symonds, "Some Unpublished Privy Seal Docquets of the Civil War Time."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. O. C. Hills, "The London Building Acts: with Some Suggested Amendments."

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's-gate, Westminster, 3 p.m. Annual Meeting. Reading of papers selected from following list:—1. Mr. J. H. Andrew, "Some Experiments upon Copper-Aluminium Alloys." 2. Mr. J. L. Haughton, "The Constitution of the Alloys of Copper with Tin." (Parts I. and II.) 3. Mr. O F. Hudson, "Etching Re-Agents and their Applications." 4. Professor A. K. Huntington, "The Effects of Heat and of Work on the Mechanical Properties of Metals." 5. Dr. G. H. Gulliver, "The Quantitative Effect of Rapid Cooling upon the Constitution of Binary Alloys." (Part III.—Conclusion.) 6. Professor A. A. Read and Mr. R. H. Greaves, "The Properties of Some Nickel-Aluminium and Copper-Nickel-Aluminium Alloys." 7. Dr. W. Rosenhain, "Some Appliances for Metallographic Research." 8. Mr. S. Whyte, "The Micro-Chemistry of Corrosion. Part III.—The Alloys of Copper and Zinc."

FRIDAY, MARCH 19...Metals, Institute of, at the Institution of Mechanical Engineers, Storey's-gate, Westminster, S.W., 10.30 a.m. to 1 p.m., and 3 p.m. to 5 p.m. Reading and discussion of papers continued.

Royal Institution, Albemarle-street, W., 9 p.m. Professor G. H. Bryan, "The Modern Piano Player—Scientific Aspects."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 8 p.m. Professors J. O. Arnold and A. A. Read, "The Chemical and Mechanical Relations of Iron, Cobalt, and Carbon."

SATURDAY, MARCH 20...Sanitary Institute, Exchange-buildings, Nottingham, 10 a.m. Discussion on "The Mothers' and Babies' Welcomes of Nottingham for Promoting Maternal and Infant Welfare."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Recent Researches on Atoms and Ions." (Lecture V.)

Journal of the Royal Society of Arts.

No. 3,252. VOL. LXIII.

FRIDAY, MARCH 19, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 22nd, 8 p.m. (Cantor Lecture.) M. H. BAILLIE SCOTT, "House Building: Past and Present." (Lecture II.)

WEDNESDAY, MARCH 24th, 5.30 p.m. (Ordinary Meeting.) LADY LUGARD, "The Work of the War Refugees' Committee." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, March 15th, Mr. M. H. BAILLIE SCOTT delivered the first lecture of his course on "House Building: Past and Present."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, March 18th; The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., in the chair. A paper on "The Indian Army" was read by LIEUT.-COLONEL A. C. YATE, I.A. (retired).

The paper and discussion will be published in a subsequent number of the *Journal*.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1915 early in May next, and they therefore invite members of the Society to forward to the Secretary on or before Saturday, March 27th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, etc.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (afterwards Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham).

In 1887, to HER MAJESTY QUEEN VICTORIA.

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S.

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

In 1892, to Thomas Alva Edison.

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S.

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S.

In 1896, to Professor David Edward Hughes, F.R.S.

In 1897, to George James Symons, F.R.S.

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S.

In 1899, to Sir William Crookes, O.M., F.R.S.

In 1900, to Henry Wilde, F.R.S.

In 1901, to His Majesty King Edward VII.

In 1902, to Professor Alexander Graham Bell.

In 1903, to Sir Charles Augustus Hartley, K.C.M.G.

In 1904, to Walter Crane.

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.

In 1907, to the Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.

In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.

In 1909, to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.

In 1910, to Madame Curie.

In 1911, to the Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.

In 1912, to the Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S.

In 1913, to His Majesty King George V.

In 1914, to Chevalier Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, March 2nd, 1915; The Right Hon. Sir George H. Reid, G.C.M.G., D.C.L., K.C., High Commissioner for the Commonwealth of Australia, in the chair.

The Chairman, in opening the meeting, said he was often asked to do things, many of which he refused and many of which he accepted—the latter sometimes most reluctantly from a sense of duty, which was about the most painful malady that anyone could suffer from. But when he was asked to preside on the present occasion he accepted at once with the greatest possible pleasure, for a number of reasons, the two principal being that the subject to be dealt with was one of the most interesting within the whole ambit of the Empire, and, secondly, that the knowledge of the author was quite as large as his subject, which was not always the case. Mr. Lindsay was pre-eminently qualified to speak on the subject of the Northern Territory of Australia, as those present would appreciate after they had heard the paper.

The paper read was—

THE NORTHERN TERRITORY OF AUSTRALIA.

By David Lindsay,

Leader of the Elder Scientific Exploring Expedition.

That portion of Australia which is the subject of the paper I have the honour to read this afternoon is known as the Northern Territory of the Commonwealth of Australia.

It is nearly one-sixth of the whole continent. All expressions of opinion as to the characteristics of the country, its potentialities and its needs contained in this paper are the result of a personal professional study extending over more than thirty years.

My first visit to the Territory was in 1878. I spent six years in the coastal regions and over four years in the interior, surveying, exploring, prospecting and reporting on the country for the Government and private persons.

In 1913 I revisited the coastal regions as a member of the Royal Commission for the Northern Territory Railways and Ports.

The first attempt made to settle the north coast of Australia was in 1825, when a military post was established at Fort-Dundas, Melville Island. Owing to the hostility of the natives the settlement was in 1827 transferred to Raffles Bay on Coburg Peninsula on the mainland. In 1837 it was again moved, this time to Port Essington, which is a very fine harbour some thirty miles deep. In 1849 this was also abandoned, and those who had survived returned to England.

From 1827 to 1863 this Territory was part of the Province of New South Wales.

On July 25th, 1862, the great explorer, John McDouall Stuart, hoisted the Union Jack on the shores of Chamber's Bay, on the north coast, having, on this his third attempt, successfully crossed the continent from south to north.

The result of Stuart's report was the erection of the overland telegraph line from Adelaide

to Darwin, 1,896 miles by South Australia, at a cost of over £470,000, establishing telegraphic communication between Australia and England, and the dispatch of a party of surveyors under Colonel B. T. Finniss in 1864 to select a harbour and town site, and survey a large area of agricultural land which had already been sold to English and colonial speculators. Owing to adverse circumstances, bad management, and a wrong selection for the settlement, Finniss's expedition was a bad failure, and cost South Australia a large sum of money.

On December 27th, 1868, the Surveyor-General of South Australia, Mr. G. W. Goyder, sailed with a party of surveyors, and in a remarkably short time selected Darwin as the harbour, surveyed the town of Palmerston on the northern plateau overlooking one of the best harbours in Australia, and surveyed half a million acres which were sold at 3*s.* 9*d.* per acre, with a town lot given in with each 320 acres. No attempt was ever made by the purchasers to settle or develop this land.

In the eighties a railway was built from Darwin southwards—a length of 146 miles—to Pine Creek, to assist in opening up the mineral fields and as part of the transcontinental line. A southern section had already been built to Oodnadatta, 688 miles north from Adelaide.

South Australia, to which province this area of 523,620 square miles—extending from latitude 26° south to 11°, and from longitude 128° to 138°, the western boundary of Queensland—had been in 1864 provisionally annexed by Royal Letters Patent, had neither the surplus population nor the money to attempt the settlement of a land which was to its nearest point 800 miles from Adelaide, the seat of Government, and by sea to its northern harbour, Darwin, over 3,700 miles. All she could do was to throw open the lands on the easiest terms and conditions, establish experimental gardens to prove what could be grown, encourage mining, open up roads, keep a staff of officials, telegraph operators, surveyors, police, and magistrates under a Government Resident.

Truly this was an outpost of the Empire. When I went there in 1878 the mails were brought in Dutch steamers at intervals of ten weeks, the voyage from Adelaide taking twenty-eight days.

In 1871-72 gold was discovered, and a mining boom set in; large quantities of alluvial gold were obtained, and in face of almost insurmountable difficulties reef mining was attempted. Mining has since been continued under great difficulties of want of capital and suitable labour.

South Australia had conceived the bold project of building a railway 1,896 miles long, connecting Darwin with Adelaide, nearly due north and south. As previously stated, the southern section of 688 miles was built, when dry seasons and faint-hearted politicians caused this great work to be stopped at Oodnadatta, in the driest region of Australia, where the rainfall is only 5 ins. per annum. A gap of 1,070 miles still remains to be bridged.

Owing to the reported richness of the soil and the cheap land, various attempts were made to effect agricultural settlement by southern people. Sugar by De Lissa failed because of the unsuitability of the soil (for sugar will not grow on ironstone ridges) and ignorance on the part of the managers. Brandt, at Shoal Bay, failed for the same reason, although the soil on his selection was better. Ouston, on the Daly River, failed for want of capital. Coffee and rubber were planted at Beatrice Hills on the Adelaide River. These succeeded admirably, and proved the suitability of the climate and soil for both these valuable products, but labour difficulties, want of transport and capital, caused their cultivation to be abandoned. In spite of the neglect, and of the fires which every year sweep over the hills, coffee bushes still live and bear berries every year, and the rubber-trees attain great growth.

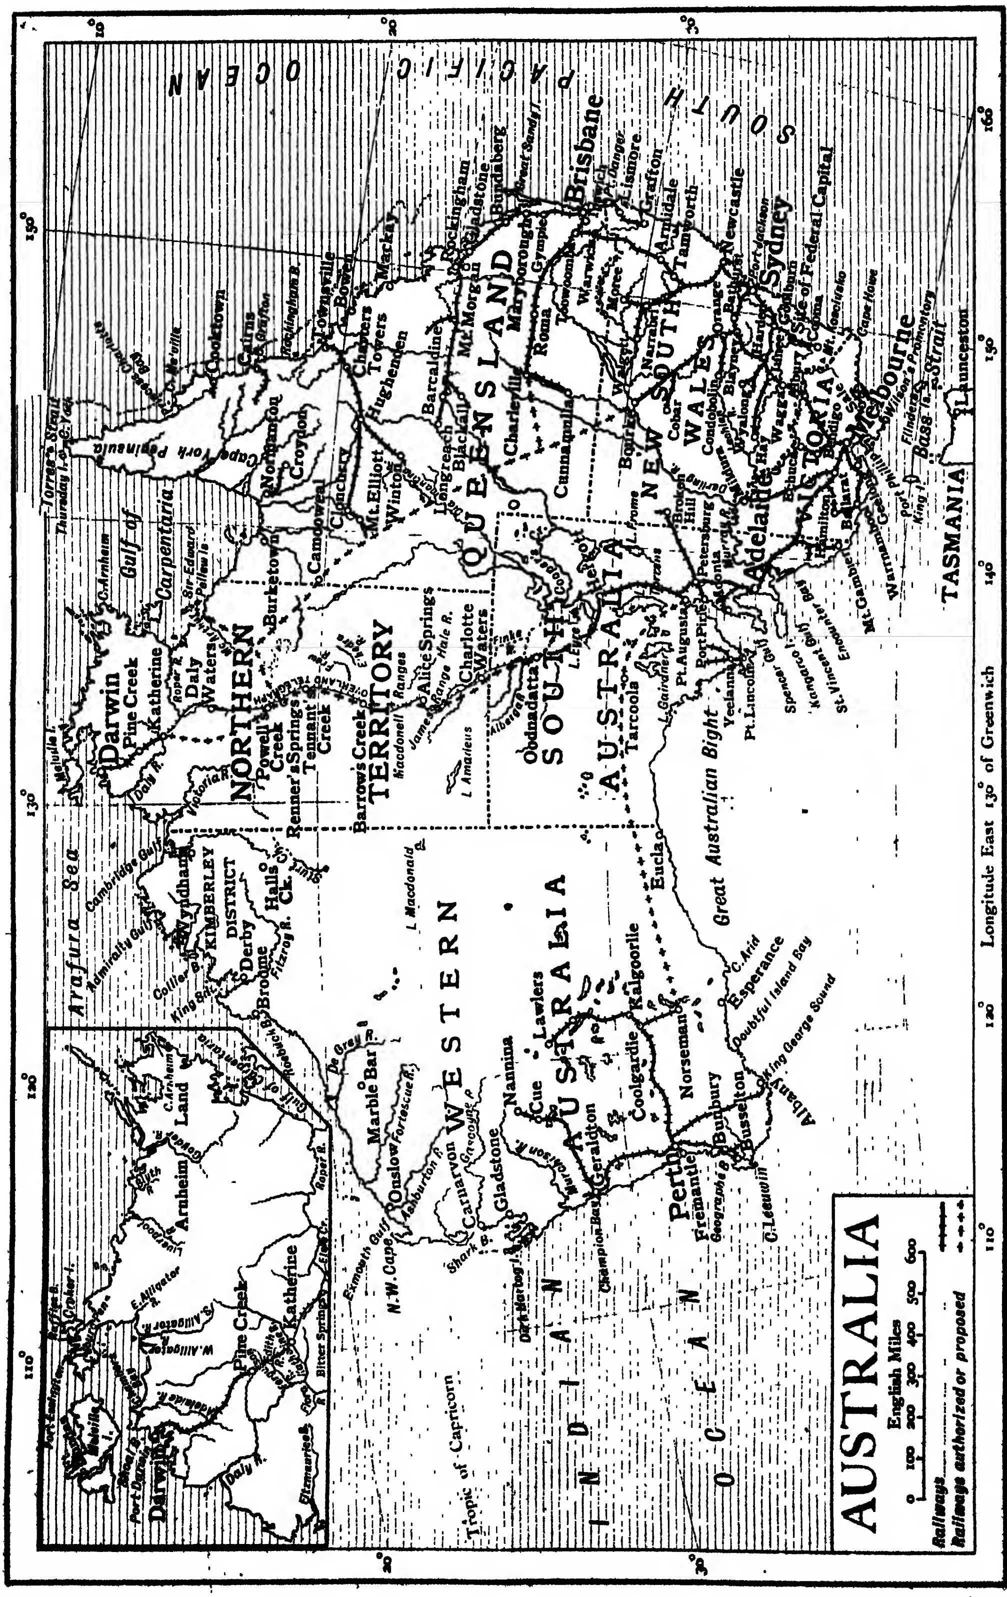
A Bill was passed through Parliament authorising the completion of the north-south railway on the land-grant system, but no businesslike attempts were made by the Government to introduce this to the notice of capitalists, and the opportunity lapsed.

When the States of Australia federated it was anticipated that the Commonwealth would take over South Australia's responsibilities and liabilities in respect to the Northern Territory, and administer and develop it. Pending this, South Australia agreed not to grant any leases or alienate any land; consequently the country made no advance for ten years.

On January 1st, 1911, the Territory was transferred to the Commonwealth under an agreement which set forth that a railway should be built connecting Darwin with Adelaide, such railway remaining within the boundaries of the Territory until it reached the southern boundary. Connections with the other States would follow.

Commonwealth Control.

In their haste to do something with this great lone land the Government of the day did not



NOTE.—The east-west line from Kalgoorlie to Port Augusta is in course of construction, and will be completed in two years.

consider what they had undertaken, but rushed into experiments.

An almost complete new staff of officers was appointed; "men with open minds and no preconceived ideas" were selected and sent up to enter at once upon certain works. Had they been given time to make themselves acquainted with a country whose conditions were quite different from anything these gentlemen had experienced, much money and some reputations would have been saved and blunders avoided.

The whole of the experience and knowledge gained by South Australia during the forty-five years she had controlled it, was turned down and treated as of no account. Consequently the past four years have not advanced settlement. Experimental farms and new conditions of land tenure have not induced many settlers to try their fortunes. Only eleven farmers have remained on their holdings.

An experimental sheep station has been established near the head-waters of the Roper River, and if success be obtained a large area of country, which at present is only considered fit for cattle, will be available for this class of stock.

A commencement has been made on the extension of the railway from Pine Creek to the Katherine River, a distance of fifty-four miles. This is a further link in the trans-continental line. Surveys and classification of lands are being vigorously carried on. A careful and systematic geological examination of the mineral areas is being made. Boring for water on the stock routes has commenced.

What of the Future?

The Royal Commission appointed to advise as to the routes of railways and new ports necessary for the development of the Territory recommended the connection of Pine Creek with Oodnadatta, as nearly as possible through the centre, a length of about 1,020 miles, thus connecting Darwin with Port Augusta and Adelaide, junctioning with the east-west trans-continental railway at Port Augusta; from a suitable point between 400 and 500 miles south of Darwin, a branch line south-easterly across the famed Barkly Tableland, to connect with the Queensland system, giving an almost direct line to Sydney, and, incidentally, all the Queensland ports; also a line about 250 miles in length from a new port to be created on the Gulf of Carpentaria, at the mouth of the McArthur River, up the valley of that river to link up with the Queensland-Darwin line. These lines would enable the whole of the Territory to be occupied, giving quick and easy access to the best ports. The total length is about 1,350 miles, and the estimated cost between seven and eight millions.

These recommendations will be given effect to, and then, and not till then, will the Territory have a chance of being settled and developed.

You will understand the isolation of this great country when I tell you that by sea Darwin is 3,700 miles from Adelaide, 3,200 miles from Melbourne, 2,620 miles from Sydney, 2,100 miles from Brisbane. It takes longer to journey from Darwin by sea to the nearest State capital than it does to go from Darwin to Singapore or Hong-Kong.

Should the traveller want to reach the great pastoral district from Melbourne, he would take steamer to Townsville, a distance of 1,800 miles; rail to Cloncurry, 480 miles; coach, 200 miles to Camooweal, which is just on the edge of the Territory, and then would find he was still 850 miles from Darwin. To reach the MacDonnell Ranges, he would travel by train 688 miles, and then by camels or horses 300 miles.

The Mining Industry.

The value of the output of minerals to date is over £2,000,000. In 1913, tin, valued at £25,526; gold, £13,256; copper, £482; wolfram, £3,140—a total of £44,626—were entered for export. Only ninety Europeans and 530 Chinese are engaged on the fields.

It is of the utmost importance that this industry be fostered and encouraged in every way. Mining gives great promise of responding profitably to fair and liberal treatment. Making roads, laying light lines of railway, erection of public batteries, subsidies for deep sinking, and large rewards for the discovery of payable mines will induce prospectors and capitalists to embark on this enterprise. It is necessary that all this assistance be controlled by an energetic and competent mining department, which I think the Territory has just now.

Mining attracts population quickly, and it has to be fed; thus a local market for the produce of the agriculturist is provided, enabling him to dispose of vegetables, fruit, rice, horsefeed (maize and lucerne), tobacco, milk, butter, and eggs, besides giving the small grazier a market for his fat stock.

Pastoral.

This industry has been established in various districts where there are natural permanent surface waters, and although the profits have

been small, owing to the great distance from the markets and the consequent low price obtainable for stock on the stations, the flocks and herds of sheep and cattle have increased year by year, until there are now over 450,000 cattle, 20,000 horses, 75,000 sheep, 8,000 goats, depasturing on the 107,406 square miles leased, which brings in the insignificant amount of £10,109 as rent. The rental for pastoral leases is very low indeed, ranging from 6*d*. to 4*s*. per square mile.

With the advent of higher prices for meat created by the overseas demand, the station holders will be enabled to improve their holdings, and depasture many times the number they now do. Increased rents will be obtainable.

The opening of stock routes by providing water, the building of railways, and the opening of a new port, as mentioned before, will open up a country capable of carrying 30,000,000 sheep and hundreds of thousands of cattle, turning a practically unoccupied country into one of the most important suppliers of meat to Britain.
